This discussion of difficulty and discrimination assumes that scoring is dichotomous; that is, that each question is scored as either correct or incorrect, with no partial credit possible. With polytomous scoring (i.e., when questions are worth more than one point, with partial credit possible), however, some adjustments must be made. First, rather than IF, we use IF*, which is equal to the average score for a given item divided by its number of points possible. We then use IF* in calculating the ID_{U-L} , B-index, or DI. Technically, this also changes the correlation coefficient being used, so that the point-biserial and phi are not being calculated. Practically speaking, however, there is no change, since these are both Pearsonian coefficients, and a computer will use the same formula. The only difference is that the correlation should technically be called a Pearson r , rather than a point-biserial. These slight complications notwithstanding, though, the interpretations for IF*, ID_{U-L} *, B*, DI*, and the two correlational estimates of discrimination are the same as for their NRT equivalents.

Distractor analysis: Item analysis, or consideration of difficulty and discrimination, tells us which questions on a test are problematic. In the case of multiple-choice tests, we can then examine the distractors (incorrect choices) on those questions to help improve them. One way to do this is to see what percentage of test takers selected each option, and then revise or replace each one that was not selected by at least 10% of the test takers (Bachman, 2004). Two other approaches involve examining the relationship between test takers' total scores and their distractor choices. The first of these methods is to calculate the point-biserial correlation of each option with total score. This is done by, in effect, "scoring" an item as many times as it has options; thus, a three-option question would undergo the process three times, once for each option. The correlation for the correct answer will, of course, be the same as the item's point-biserial estimate. The correlations for the distractors, on the other hand, should all be negative. A *positive* correlation for a distractor is problematic, particularly if it is not close to zero—that is, if choosing a particular incorrect option is associated with having a higher score on the test, then something is clearly wrong. A final method is to compare the proportions of test takers in the high and low groups (the same ones as are used in the ID, B-index, or DI) who selected each distractor.

Third, we turn to analyzing rating scales and raters. When analyzing scores based on ratings, we are concerned with both inter-rater consistency (how similar the ratings are that are produced by different raters), as well as intra-rater consistency (how consistent each rater is; that is, whether the rater would give the same score at different times or on different occasions).

Perhaps the simplest approach to estimating the consistency of ratings is to correlate sets of ratings. This correlation is often reported by itself, but to be used as a reliability estimate, it should be adjusted using the Spearman-Brown prophecy formula. When there are more than two ratings, the Fisher Z-transformation should be applied to each correlation, the correlations then averaged together, and the result retransformed to a correlation coefficient. Another approach that can be used when there are multiple scores (for multiple raters, multiple tasks, or for individual subscales of an analytic scoring rubric) is to calculate Cronbach's alpha as an estimate of the internal consistency of the ratings.

4 STATISTICAL ANALYSIS OF TEST RESULTS

A more informative approach is to use generalizability theory to estimate the consistency of scoring. This offers the added advantage of identifying which facets of the measurement process are contributing most to unreliability. The main disadvantage of using generalizability theory is that it requires a greater degree of technical expertise. The same is also true of many-faceted Rasch theory, which can be used to complement generalizability theory. Its greatest advantages are that it provides ability estimates for each test taker, and difficulty or severity estimates for each rater, task, or rubric subscale. It can also provide diagnostic information on whether individual raters are showing more or less variability in their ratings than would be expected.

In “messy” rating situations, those in which there is inconsistent overlap in terms of which rater scored which test takers, the rater agreement proportion (RAP) can be used. This is the proportion of ratings for a given task (essay, spoken response, etc.) that are the same; for example, if three out of four ratings are the same, the RAP is .75.

Fourth it is important to understand differences in group performance. When different test-taker groups take a test, some groups may perform better than others on some test items. These groups may self-report memberships through a questionnaire (examples of self-reporting are gender, race and ethnicity, age, native language, second language learning, etc.), assigned by a test designer (examples, test accommodations, planning conditions, computer use, etc.) or assigned by a researcher in an experimental research setting (examples, experimental group versus control group; treatment 1 group versus treatment 2 group, etc.).

The analysis of variance and *t* test statistics can provide information as to whether group differences on certain test items or tasks are statistically significant. Test-score differences among test-taker groups will normally also require an examination of test bias.

Generalization

To evaluate the assumptions associated with generalization, test scores need to be analyzed in terms of their reliability, dependability, and generalizability. In NRT, the concern is with the consistency of scores (technically, consistency of ranking, but in practice it is generally treated as consistency of scoring), which is referred to as reliability. In CRT, we are concerned with two areas of consistency, both referred to as dependability. The first is the dependability of scores, and the second is the dependability of classification. In general, however, it is important to provide an index of score consistency (and classification consistency, for CRT), as well as an estimate of the margin of error associated with the estimate (for NRT, the standard error of measurement, or SEM; for CRT, the criterion-referenced confidence interval, abbreviated the CRT CI or CI_{CRT}).

Two important alternative paradigms for looking at measurement consistency have been developed in the last few decades: generalizability theory (G theory) and item response theory (IRT). Generalizability theory is particularly suited to analyzing rated performances, as in tests of speaking or writing, but is not limited to these contexts, however. G theory can be used to analyze both NRT and CRT results, and also provides estimates of the margin of error for test scores, as well as classification consistency for CRTs. IRT is particularly suited for working with large (i.e., numbering hundreds or thousands) test-taker groups. Detailed explanation is beyond the scope of this entry, but it is important to mention an IRT variant known as the many-facet Rasch model, which is particularly useful with rated performances.

Explanation

To support explanations of score meaning the key applications of statistics are explaining the constructs being assessed, explaining test performance, and conducting concurrent validation studies. One way of looking at score meaning is through an analysis of the

composition or structure of the scores; whether the test structure (or language abilities as operationalized in the test) is unitary or divisible (or multicomponential). This can be examined through exploratory factor analysis (EFA), which seeks to identify hypothetical factors that account for the patterns of correlations that are observed in test scores (from individual items or tasks). In confirmatory factor analysis (CFA), a proposed test structure is specified in advance and the data available in the form of test scores are used to evaluate it. Structural equation modeling can also be used for this purpose (see Kunnan, 1995, 1998). Concurrent validation studies are conducted by examining how well a new test's scores correlate with some other test's scores that have already been demonstrated to be useful in decision making, or have been demonstrated to be a good measure of the intended construct. Such studies use correlations to analyze the data.

Utilization

The utilization portion of a validation argument needs to provide support for the intended test uses. Statistics are helpful in this area in standard setting, estimating classification errors, and understanding test consequences and washback.

When test takers receive scores for their test performance, they are typically accompanied by other classifications such as "pass" or "fail," or categories or levels of performance (such as "needs improvement," "basic," "proficient," "advanced," or "unqualified," "qualified" and so on). These classifications are based on standards that have been set either in terms of pre-specified percentages of "pass" or "fail" (such as 5% or 10% pass rate) as in NRTs, or pre-specified performance or content standards (operationalized in terms of cut-points or cutoff score) as in CRTs. While both types of standard-setting procedures need to be defended, performance and content standards are more complex because the procedure involves many steps and a clear research design. Understanding consequences and washback are other ways of appreciating the effect of utilization or decision making of the test.

Software and Reporting

Software

Many software programs, some general and others written specifically for assessment, can be used for analyzing test results. For entering, organizing, and cleaning data, Microsoft Excel or a similar spreadsheet is a simple, easily available, and easy-to-use choice. It also provides adequate descriptive statistics, has very powerful features for creating graphs, and can calculate the Pearson r , although non-Pearsonian correlations must be calculated manually. For anything beyond the simplest statistics, however, a true statistics package should be used. Some of the most common ones are IBM SPSS Statistics (formerly SPSS), STATA, BMDP, R, and SAS.

For NRT and CRT item and distractor analyses, Microsoft Excel can be used fairly easily, and can also be employed for calculating reliability (Carr, 2011). As for software specifically developed for handling reliability and item analysis, Lertap and ITEMAN are two commonly used packages. Lertap runs within Microsoft Excel, taking advantage of its file formats, output options, and familiar interface. ITEMAN, on the other hand, works with ASCII-format data files.

For generalizability theory, while the basic estimates can be calculated using results from general statistics packages, there are three packages developed by Brennan that are available for free and can calculate results automatically—aside from calculating proportions of variance, which requires manual addition and division by the user. These are GENOVA, the original program; urGENOVA, which accommodates unbalanced designs;

and mGENOVA, which accommodates both unbalanced and multivariate designs (e.g., when there are multiple subscales within a rubric).

For IRT, BILOG and MULTILOG are perhaps two of the best-known packages, with BILOG used for handling dichotomous data, and MULTILOG for polytomous items. The program PARSCALE, on the other hand, can apply both dichotomous and polytomous models. Two well-known programs for applying the many-facet Rasch model, as opposed to IRT models in general, are FACETS and WINSTEPS.

For factor analytic studies, IBM SPSS Statistics can be used to perform exploratory factor analyses. Other programs are needed, however, to perform confirmatory factor analyses and structural equation modeling (SEM), the best-known are EQS, LISREL, AMOS, and M+.

Reporting

Reports of statistical analysis results should contain descriptive statistics and correlations among all the variables. The number of decimal places to be reported generally depends upon the scale of the variables, but for correlations, two or three places is the norm, although five places is appropriate if the correlations might be used as data for factor analytic studies replicating or extending the project. Test- or survey-based studies should include reliability or dependability estimates for the overall test or survey, as well as for each section or scale for which separate scores are reported. Each reliability or dependability estimate should be accompanied by its corresponding CRT confidence interval or standard error of measurement.

In reports or papers discussing CFA or IRT results, model fit must be discussed. In these studies, as well as in those using EFA, it is also important to explain how the final model was developed, how it compared to other plausible models, which other models were considered, and why they were rejected. Factor loadings should be reported in all factor analytic studies, as well as any correlations among factors. In the case of CFA and SEM studies, diagrams or figures of models are important for ease of understanding by readers. All journal articles or research reports based on factor analytic studies, particularly those employing CFA and SEM, should include an appendix containing the correlation or covariance matrix and standard deviations of all variables included in the study. This information is essential in allowing others to replicate and verify results.

Conclusion

These statistical analyses of test results provide an overview of the types of procedures that are used to investigate how tests perform with particular groups of examinees. These types of analyses are needed to build a validity argument which supports the links that test users hope to be able to make between test performance, test-score interpretations, uses, and decisions. Only fundamental statistical procedures used in standard test analysis contexts were included in this entry. Variations in test constructs, research design, data collection, and research questions might need approaches not discussed here.

Status Planning

SUE WRIGHT

Status planning concerns itself with the conscious choice of the variety(ies) that will become the official language(s) of the state, the medium of its institutions, and the means for interaction between state and citizens. As an activity it is a recent phenomenon, only appearing in its present form with nation building and the nation-state.

It occurred first in Europe, where the nation-state model developed. As the concept of nation-state spread, so too did the ambition to achieve congruence of territory, people, and language within the state. National elites worldwide foster national linguistic homogeneity.

Status planning may, however, prove to be a short-lived phenomenon. In the early 21st century, the political landscape has changed. In many ways we are entering a postnational era and the new context may not be as favorable to top-down language planning as the nation-state era.

Feudal Europe

Status planning did not exist as such in medieval Europe. The feudal system developed language practices organically and there was no central decision-making process influencing language choice. The three main classes (nobility, clergy, and peasants) were not linguistically homogeneous. Those at the very apex of the ruling class acted on a European stage, marrying, inheriting, making alliances, and waging war across the continent. The great dynasties were multilingual, as were the lesser aristocrats in their retinues.

The clergy was another pan-European group. Priests and members of religious orders were at the very least bilingual with knowledge of the sacred language as well as their first language. Catholic monks and priests were all under the authority of the pope in Rome and even the lowliest parish priest knew a little Latin, the sacred language, and could interact with fellow Catholic clergy from any country. The Orthodox Church also centralized authority and had sacred languages that acted as *lingua francas*.

The third and most numerous class, the peasantry, was, in contrast monodialectal. Anchored on the land, under the control of their feudal lord and rarely traveling far from home, peasants used dialects with limited territorial reach. Europe before 1500 thus presented a linguistic landscape where difference came from class and calling. We cannot yet discern linguistic cohesion within polities nor a mosaic of national linguistic groups.

The State-Nations

Linguistically homogeneous nation-states began to develop in the 16th and 17th centuries, as monarchs in the west of Europe wrested power from their aristocracies, fixed the borders of their states, and centralized authority in their capitals. The feudal system crumbled, law was no longer a local affair, and the state was increasingly administered by a new breed, the literate, secular bureaucrat. Increasingly these administrators abandoned Latin as the language of literacy to work through the prestige vernaculars—the languages

of the king, the court, and the major commercial centers. In France, this was the dialect of the Ile de France; in England, the dialect of the southeast Midlands; in Spain, the dialect of Castile. They were soon to be confirmed as languages of power in early examples of status planning. François I enshrined his own variety of French as the language of state by the Edit de Villers-Cotterêts in 1539. In 1535, Henry VIII ruled that all agents of the crown in Wales were to use English in official settings.

Other developments aided the standardization and spread of these prestige vernaculars. The introduction of printing to Europe in the late 15th century provided a technology that allowed cheap reproduction of texts. From the early 16th century, the controversies of the Reformation encouraged literacy. People wanted access both to the sacred word and to interpretations of it. The printers anxious to sell the product to the largest market possible would not supply translations in dialects with small numbers (Anderson, 1991). People's desire for the sacred texts overrode their reluctance to read in a dialect that was not quite their own.

For two centuries spread of the standardized languages of state was limited to the growing middle class. A diglossic situation developed and only began to disappear when there was profound political and economic change. This came when the doctrine of the monarch's "divine right to rule" was challenged, for example in the English Civil War, the American War of Independence, and the French Revolution. For the first time since antiquity, the masses were to be involved in governance. Consulting and informing the "sovereign people" was, however, problematic. The population was still massively rural, still speaking local dialects.

In France, the revolutionary government soon realized the massive task confronting them if the "people" were to be consulted. Only a minority spoke French (Grégoire, 1794). At first all communications were translated into the various languages and dialects of France. Then, in 1793, the revolutionary government changed policy and reconfirmed the Edit de Villers-Cotterêts. Using French became a patriotic duty, a sign of loyalty to the Revolution. There is, of course, a big jump between making a status planning decision and implementing it. It was another century before the revolutionaries' language policies were realized. The most significant step toward a French-speaking France was free, obligatory, French-medium primary education, introduced in the 1880s. The official language of the state also spread as a side effect of other developments: industrialization and urbanization drove the rural population from the isolation of their villages into the linguistic melting pot of the towns and cities where the national language acted as a *lingua franca*; citizen armies brought conscripts together and encouraged acquisition and use of the national language; greater democracy required media for the nation-wide debate necessary before elections and referenda. Top-down planning together with spin-off from these other processes brought about national communities of communication. Most moved to the national standard because linguistic unification fitted with the prevalent ideology and was seen as part of national identity and patriotism. Those who did not accept it (or who were excluded) have suffered to a greater or lesser extent, always viewed as minorities and not fully part of the national group.

The Nation-States

The ideal of sovereign peoples ruling themselves in their own inalienable territories proved an intoxicating idea. In Germany, Herder (1784) argued that a nation was a natural state of affairs, its members molded by their geographical niche, shaped by their own exclusive history, speaking their own unadulterated language and needful of their own sovereign territory. This line of reasoning approaches the idea of congruence of language, people,

and state from the opposite direction. Rather than fixing frontiers and then legislating to encourage homogeneity, nation building became a homogeneous people's search for discrete territory. The problem in this ideology was the concept "language." Where geographically did a "language" start and stop? "German," for instance, was spoken from Friesland to the Baltic, from Schleswig-Holstein to Switzerland, from Alsace to Austria. Did all these speakers constitute a nation? They already possessed a common standard written language, *Hochdeutsch*, which Luther's translation of the Bible in the 16th century had played a role in establishing. In the event the German nation-state formed in 1871 was not a home for all German speakers. Its Prussian leaders adopted ethnolinguistic criteria for membership only insofar as it suited their broader political strategy.

Nonetheless, Herderian ideology inspired central and eastern Europe throughout the 19th century. The idea that a sovereign people should have its own territory and that any exterior power that tried to dominate it should be resisted had powerful appeal in this part of Europe, divided among the Russian, Austro-Hungarian, and Ottoman empires. However, before proto-elites could begin to mobilize for self-determination, their proto-nations had to be brought to an understanding that they were discrete groups. The communication challenge was the same as that faced by the French revolutionaries. As Tom Nairn (1977) famously put it, "the elites had to invite the masses into history and the invitation had to be written in a language that they could understand." So language planners played a key role in the process. Linguists codified and standardized the dialects designated as national language, aiming to promote the greatest possible comprehension within the "nation" and to provide a clear demarcation from neighbors on the language continuum (Kloss, 1967). The "national" language was spread through education in the vernacular. Songs, folktales, and legends in dialect were collected and written down in the new standard. The political project of independence was elaborated in the national language. And from the Balkans to the Baltics there was growing national awareness. When the treaties at the end of World War I broke up the defeated empires and established a number of new nation-states in central and eastern Europe, their elites thus had national languages in place, ready to be designated the official languages of the new polities.

The Nation-State as World System

The ideology of nationalism spread worldwide. In the 19th century, revolutionary movements in South America were successful in wresting power from the imperial powers of Spain and Portugal. In the 20th century, the ambition to be a sovereign people in an independent state swept through Africa and Asia, and the French, Dutch, and British empires were dismantled. Immediately these new nation-states began nation building. Most had diverse populations because of the frontiers created by colonialism. The situation resembled the case of the state-nations, namely, several cultural/linguistic groups found themselves together as citizens under one law and one set of institutions. New governments copied the language planning of European nation building and mostly opted for state monolingualism. Some chose languages that had their origins as regional lingua franca, others the former colonial languages, in order not to give any single autochthonous group linguistic advantage. However, status planning has generally proved unsuccessful in the multilingual settings of Africa, Asia, and South America. The adoption of a single language of state has tended to reinforce class divisions within society rather than create a cohesive community of communication. Many states seem to be in the phase between planning decisions and policy implementation. For example, not all states can yet provide education for all in the state language. Of course, as mentioned above, the realization of policy process took some time in Europe; in France it was a full century before the revolutionaries' aim of placing

a French-speaking school teacher in every village was finally achieved. So, based on this experience, language planning may yet prove successful in the younger nation-states.

Moving Beyond the Nation-State

However, there are a number of other reasons why the process may be different; indicators suggest we are moving into a new era where the nation-state system is not the exclusive political frame. A nation-state could be defined (see Özkirimli, 2000) as a territory with stable borders which possessed a national government that was the sole authority for its citizens; a domestic market protected by quotas and tariffs; a national defense force, staffed through conscription; a population that identified with the state through the complex influence of national media, a national education system, a standardized national language, and national symbols and icons. We are now witnessing how these factors are changing:

- National governments are no longer sole law giver and law enforcer for citizens. Human rights increasingly take precedence over national governments' jurisdiction where there is abuse. The United Nations (UN) has sanctioned intervention within sovereign territory and brought political or military leaders before its international courts.
- The end of communism allowed the free market model to penetrate every part of the globe. The World Trade Organization pressurizes states to open up their domestic markets to foreign competition. Regional groups have set up common markets; the EU (European Union) provides the most developed example with free movement of people, capital, goods, and services within its external borders.
- The cataclysmic wars of the 20th century provoked widespread dissatisfaction with the nation-state system and the ethnocentrism it encouraged. Attempts have been made to construct an international forum for resolving disputes; a state under threat can appeal to the United Nations. Today national governments rarely rely solely on their own defense forces; many belong to regional defense organizations such as NATO (North Atlantic Treaty Organization). The system is far from perfect or complete, but it is also a long step from former reliance on "balance of power" diplomacy and the defense capability of national armies.
- National media focused attention on the national scene and played an important role in the construction of national identity (Anderson, 1991). In a globalizing world flows of information and webs of contacts now cross borders. The Internet permits millions of individuals based anywhere in the world to interact in real time. Satellite and cable television construct transnational audiences in varied geographical locations. Those who are literate and have access to the hardware and electricity necessary are able to break free of national constraints.
- Education was the bedrock of nation building. Elites were largely formed in national universities. Only a tiny number of intellectuals and artists could aspire to global experience. This is no longer the case. In 2008 over 3.3 million tertiary students were enrolled outside their country of citizenship (OECD, 2010).

In all of these internationalizing projects and processes the high boundary fences of the nation-state are being dismantled. Individuals are increasingly likely to find themselves asked to be a member of transnational teams and act in international or supranational forums. The question then arises: in what language can contact take place? In all transnational settings there has been a steady trend toward use of a lingua franca. This is, at the present moment, English.

There are several points to make about the spread of English as a global lingua franca. First, people gravitate to one lingua franca; they do not see the need to learn many lingua

francas. Thus although international and supranational bodies officially designate a number of languages as their official languages, the growing tendency is to use English. This is to be noted in the UN, where Arabic, Chinese, English, French, Russian, and Spanish are official languages. It is also occurring in the EU, where the official languages of all member states are also official languages of the EU, and where there have been immense efforts to achieve multilingualism.

Second, where national bodies have made determined efforts to halt the encroachment of English within the state, citizens have often rejected such policies and found ways of countering them. The French government brought in laws to protect use of French in the public space in 1975 and again in 1994. French citizens have, however, flouted much of the legislation (Ager, 1998) and the language loyalties of the nationalist era seem attenuated.

Third, where individuals see English as a means of their (or their children's) social promotion they demand access to it. English seems a necessary if not sufficient factor in entry to elites. In 2002 the Malaysian government began an experiment to teach mathematics and science subjects through English language. In 2010 the policy was abandoned, but the following year, 2011, saw a vociferous campaign in Malaysia (<http://thestar.com.my/>) to reverse this decision. In India, the Dalits are lobbying for English-medium education, seeing in it the opportunity to break out of their low social position (Babu, 2010). The pro-English lobby argues that if the state does not supply English-medium education, then parents with the means to do so will turn to the private sector and the class divide will be reinforced by language skills.

We cannot yet know the linguistic outcomes of the new global context and there are certainly too many economic and political uncertainties to say whether the move to English as a second language will continue or falter. However, it is safe to predict that status planning cannot play a central role in restricting a lingua franca. At the supra- and international level of interaction all language change is likely to be organic and unplanned, since there is no acknowledged authority that can rule on cultural and linguistic matters. At the state level, language planning will only be accepted if it coincides with new patterns of behavior and identity, new social pressures, and the individual's personal project in the globalizing world.

We thus have a new development in status planning. Whereas measures to introduce the national language to national groups were immensely successful, attempts to maintain linguistic equality among states or to contain the spread of English as a lingua franca have been spectacularly unsuccessful. The lesson to draw from this seems to be that status planning delivers when it is in accordance with other phenomena. Learning and using the national language supported the adoption of nationalism as an ideology, patriotism as a way of being, as well as aiding social promotion within the nation-state. In a globalizing world, people seek the linguistic means to enter the virtual and actual networks of the new context. They want access to global flows of information. They refuse to be denied the opportunity to gain the linguistic skills that seem to be a prerequisite to benefiting from globalization, in order to maintain the old ideal of congruence of language territory and people.

Strategies of Translation

SANJUN SUN

The term “strategy” in “translation strategies” is often used synonymously with such terms as “procedure,” “technique,” “method,” “tactic,” “approach,” and so forth. Their meanings overlap, and translation researchers define them in various ways. Despite the terminological confusion, discussions of translation strategies can be traced back to Cicero’s advocacy of sense-for-sense translation in 46 BC, and are widely covered in translation textbooks for their pedagogical significance. This topic also relates to broad theoretical issues in translation studies.

Researchers have attempted to distinguish translation strategy from its synonyms, and to develop their own classifications from different perspectives. For example, Lörscher’s (1991) classification is based on a cognitive approach, while Chesterman’s (1997) differentiation uses a textual approach. Yet, the conceptual confusion has not been dispelled. This entry tries to distinguish translation strategies, techniques, and procedures, and to consolidate existing classifications.

It seems that clear-cut definitions of these terms might not work as well as prototype definitions. Most researchers would agree that the two prototype translation strategies are literal translation and free translation. The former focuses on the level of words, while the latter goes beyond the word level and emphasizes the creation of a target text that sounds natural in the target language. These two strategies are described in a variety of oppositions: word-for-word translation versus sense-for-sense translation; source-oriented translation versus target-oriented translation; direct translation versus oblique translation (by Vinay and Darbelnet); adequacy versus acceptability; formal equivalence versus dynamic equivalence (by Eugene Nida); semantic translation versus communicative translation (by Peter Newmark); overt translation versus covert translation (by Juliane House); documentary versus instrumental translation (by Christiane Nord); foreignization versus domestication (by Lawrence Venuti), and so on. While these binary oppositions have much in common, they reflect different perspectives and emphasize different translation aims and effects. For instance, word-for-word translation and sense-for-sense translation are text-level or segment-level strategies. Nida’s (1964) formal equivalence versus dynamic equivalence is mainly from a linguistic perspective and involves reader response. The domesticating translation versus foreignizing translation pair, proposed by Venuti (1995), reflects a cultural interventionist perspective. The two strategies affect the choice of text for translation as well as the translation process. Venuti advocates the foreignizing strategy in order to “register the linguistic and cultural differences of the foreign text” (1995, p. 81) and combat the cultural dominance of readers in dominant cultures such as the USA.

The “literal versus free” debate has been one of the central issues in translation theory and criticism throughout the ages. However, it is now generally believed that this dichotomous debate is relatively sterile, as the two strategies are part of a continuum (Hatim & Munday, 2004, p. 230), and the selection of a strategy is a function of the theoretical assumption of “what is a translation” text type (e.g., serious literature, children’s literature, technical texts, print advertisements), domain (e.g., IT, legal), function (e.g., for publication, information, or light entertainment), prestige of the source text (e.g., the Bible, pulp fiction), motivation (e.g., payment), and other factors (or constraints).

2 STRATEGIES OF TRANSLATION

Having discussed the two prototype strategies, let us turn to the definitional question: what is a translation strategy? Lörscher (1991), Chesterman (1997), and other researchers agree on a few defining characteristics of a translation strategy: (a) it is goal-oriented, (b) it is problem-centered, (c) it requires making coordinated decisions, (d) it is potentially conscious, and (e) it involves text manipulation. The aforementioned two prototype translation strategies have these characteristics. Since a translation strategy involves problem solving, a categorization of translation problems would correspond to a categorization of translation strategies. The difficulty with this, however, is that there are a number of ways in which problems can be categorized. For instance, the categorization criterion can be the prior knowledge required to solve them, the nature of the goal involved, and the complexity of the problems involved (Robertson, 2001, p. 6).

Problems, according to their scale, can be divided into global (or general) problems and local (or specific) problems. Jääskeläinen (1993, p. 116) makes a corresponding distinction between global strategies (i.e., "the translator's general principles and preferred modes of action") and local strategies (i.e., "specific activities in relation to the translator's problem-solving and decision-making"). Global strategies might be dictated by or with the commissioner while local strategies are up to the translator. In addition, local strategies are designed to handle specific problems and need to be consistent with the chosen global strategy. Jääskeläinen found that global strategies are much more frequently and consistently used by professional translators than by nonprofessionals.

From Jääskeläinen's perspective, literal and free translation strategies are global strategies since the translator has to think about the goal of the translation and how the target text should affect the readers. The global strategy chosen will affect the translation process. Since local strategies are immediately followed by specific techniques, which affect the translation result and the micro-units of the text, and are classified by comparison with the source text (Molina & Hurtado Albir, 2002, p. 509), local strategies are basically translation techniques. As translators grow in competence, some former translation problems will no longer present an obstacle to them; some of their local strategies become semiconscious or unconscious, and the use of certain techniques to cope with certain problems is automatized.

Vinay and Darbelnet's (2000) taxonomy of translation techniques (which they call "procedures") has a wide impact. They did a comparative stylistic analysis of French and English, and divided the seven procedures they discovered into two general strategies: direct/literal translation and oblique translation. The former includes: (a) *borrowing* (i.e., borrowing a word or expression from the source language, such as the Chinese word "kung fu" in modern English); (b) *calque* (which is a kind of borrowing whereby the structure of the original word or phrase is maintained but its morphemes are replaced by those of the target language; for example, the Chinese word "motian dalou," literally "sky-scraping big building," is a calque of skyscraper); (c) *literal translation*. Oblique translation includes: (d) *transposition* (i.e., changing the word class or grammatical structure without changing the meaning of the message, as in rendering a noun in the source text into a verb in the target text); (e) *modulation* (i.e., changing the point of view or cognitive category in relation to the source text, as in rendering a negative construction into a positive one: "not complicated" becomes "easy"); (f) *equivalence* (e.g., translating "to kill two birds with one stone" into Chinese as "to kill two eagles with one arrow"); (g) *adaptation* (i.e., a shift in cultural reference when the type of situation being referred to by the source text is unknown in the target culture, such as using the word "seal" for sheep when translating the Bible into Inuktitut).

Among local translation strategies, Chesterman (1997) distinguishes between comprehension strategies (for understanding and analyzing the source text) and production strategies (for the production of the target text). From a linguistic perspective, he divides production strategies into mainly syntactic/grammatical, mainly semantic, and mainly pragmatic, with

each category containing 10 techniques. Syntactic strategies involve purely syntactic changes, manipulate form, and include such techniques as calque, transposition, and sentence structure change. Semantic strategies mainly pertain to changes concerning lexical semantics. They manipulate meaning and contain techniques such as synonymy, emphasis change, and paraphrase. Pragmatic strategies have to do with the selection of information in the target text, and often involve syntactic or semantic changes as well. Pragmatic strategies include cultural filtering, explicitness change, information change, transediting, and so forth. Some of these techniques are obligatory during translation in a given language pair, while most are optional.

Many researchers (e.g., Lörscher, 1991) believe that a translation strategy is a procedure or a sequence of actions. However, this is not consonant with the dictionary definitions of strategy. According to the *Oxford English Dictionary*, strategy refers to “a plan for successful action based on the rationality and interdependence of the moves of the opposing participants,” while procedure is defined as “[t]he fact or manner of proceeding with any action, or in any circumstance or situation; a system of proceeding; proceeding, in reference to its mode or method; conduct, behaviour.” Krings (1986, p. 268) defines translation strategies as “potentially conscious plans for solving a translation problem.” Strategies involve adopting procedures to solve problems, and the chosen procedure will influence the result.

Now let us turn our attention to translation procedures (referred to as “translation strategies” by some researchers) and procedural steps. Gerloff (1986) identified the following text processing strategies: (a) problem identification, (b) linguistic analysis, (c) storage and retrieval, (d) general search and selection, (e) inferencing and reasoning strategies, (f) text contextualization, (g) editing, and (h) task monitoring. In his empirical studies, Lörscher (1991) recognized 22 elements constituting translation strategies (or procedural steps), including nine original ones and 13 potential ones, such as realizing a translational problem, preliminary solution to a translational problem, and the mental organization of source-language text segments. During the translation process, these elements are combined by translators into *basic structures*, *expanded structures*, or *complex structures* of translation strategies. He found that professional and nonprofessional translators differ in the distribution and frequency of the strategies employed, but do not differ qualitatively; that is, their mental processes do not reveal significant differences. He concluded that it is impossible to ascertain “[w]hen faced with problem X, [translators] employ strategy Y,” but we can find out “[w]hen several [translators] are faced with a problem X, many or most of them employ similar or the same types of strategy” (p. 280). Darwish (2008) identifies four distinct translation procedures employed in translating: recursive strategy (i.e., a circular and revisional process), waterfall strategy (i.e., a sequential unit-by-unit process), stop-and-go strategy (i.e., a block-by-block process), and mixed strategies (i.e., a combination of the previous three strategies).

In some translation textbooks (e.g., *Thinking German Translation: A Course in Translation Method* by Hervey, Loughridge, & Higgins, 2006), “translation method” is often used as a cover term for “translation strategy,” “translation technique,” and even “translation procedure.” For instance, there are literal and free translation methods. Compared with translation strategies, which are highly individualistic, translation methods are supra-individual and well tested (Lörscher, 1991, p. 70). However, “translation method” in English is often associated with such modes as machine translation and computer-aided translation. The term “translation approach” is often used in a vague sense, while “translation tactic” is rarely used.

Discussions of translation strategies before the 1980s were primarily prescriptive, and researchers tended to argue for one translation strategy against another. Since the 1980s, empirical research into translation strategies, techniques, and procedures has become

increasingly common. There are two major empirical approaches in this regard: product-oriented and process-oriented. The former approach mainly refers to corpus-based contrastive analysis: a parallel corpus consisting of source texts and translations is built for analyzing the frequency of shifts (i.e., textual differences between source text and target text) and the various translation strategies and techniques employed. The factors to be considered can include text type, domain, synchronic and diachronic variation in language features and translation norms, idiosyncrasy, certain language features (e.g., metaphors, allusions), among others. In a process-oriented approach, translators are usually asked to translate a passage while thinking aloud, and the process will be recorded and then analyzed. The factors that might influence the frequency and distribution of translation strategies and procedures may include translation competence (e.g., novice translators versus professional translators), language direction (i.e., from or into the mother tongue), text type, domain, translation brief, translation difficulty level of the test passage, time pressure, and so forth. These factors need to be manipulated or kept constant in an experiment in order to make meaningful comparisons.

In PACTE's (2003) translation competence model, strategic competence (for solving problems and optimizing the process) is the most important sub-competence among five sub-competencies (i.e., bilingual, extralinguistic, knowledge about translation, instrumental, and strategic). Investigating translation strategies will have significant pedagogical implications and may benefit research on machine translation.

Structural Equation Modeling

ROB SCHOONEN

Structural equation modeling (SEM) refers to a flexible and rich analytic approach that can be used to address a variety of research questions through a combination of factor analysis, analysis of variance (ANOVA), and regression analysis. Although not (yet) widely used in applied linguistics, SEM has been applied in research to test complex hypotheses about performance levels of groups, relationships between variables, and the invariance of these relations across various groups, such as different first language (L1) groups, age groups, or proficiency groups. For example, the contributions of syntactic skills and vocabulary knowledge to reading proficiency might differ for L1 and second language (L2) speakers. SEM provides means to test whether the contributions for these two constituent variables are the same across groups (see Van Gelderen et al., 2003). SEM also helps in investigating direct and indirect relations between dependent and independent variables in language research. Beron and Farkas (2004) studied the extent to which oral skills affect the reading success of young children directly and the extent to which these oral skills are the mediating variables when it comes to the effect of race and mother's education on reading success in school. Using SEM, the researchers were able to design a complex model and to test it against the available empirical data, showing that the oral skills are indeed an important mediating variable for class and especially race effects.

Furthermore, correlations and regressions in common analyses with observed scores may be attenuated by the unreliability of the observed scores. SEM provides means to take the measurement error into account. Thus, the researcher is likely to draw conclusions that are more valid in the sense that they are not affected by measurement error.

The general approach in SEM is modeling relationships between observed variables, hypothesized underlying latent variables, or both. The input for the analyses is raw data from which variances and covariances (i.e., unstandardized correlations) are derived. Other terms than SEM that have been used to refer to this technique include "covariance structure analysis" and "causal modeling." SEM can be conducted using software packages, such as Lisrel, EQS, AMOS, or Mplus. In the remainder of this entry, the layout of a structural equation model consisting of a structural model and a measurement model will be briefly discussed, as well as the selection and evaluation of a preferred model among plausible choices. Next, a few special applications will be introduced to illustrate the flexibility of the approach. Finally, the most important (statistical) assumptions underlying the use of SEM are presented and a few cautionary comments are made.

Modeling Data

To be able to use SEM, a researcher has to be explicit about the model that is expected to describe the relations between all theoretical variables involved. This part of SEM is called the *structural model*. The theoretical variables are often operationalized by one or more test scores or questionnaire data. The relationships between these so-called observed or manifest scores and the theoretical or latent variables are modeled in another part of the SEM, the *measurement model*. This latter part addresses the question of whether the observed test scores available for, for example, language achievement can indeed be considered as

2 STRUCTURAL EQUATION MODELING

indicative of a single consistent underlying (latent) variable. Having operationalized the theoretically relevant variables, the researcher can address in a structural model how the latent variables relate to each other.

Standard procedures such as ANOVA and multiple regression analysis can be considered special cases of SEM (Hoyle, 1995; Kline, 2005). In all cases there are dependent variables, the scores the researcher tries to explain, either by a categorical variable (e.g., gender; ANOVA) or by one or multiple predictor variables (regression analysis). Also, the relationship between a set of variables and a hypothesized underlying factor, commonly explored in factor analysis, can be more extensively investigated with SEM by specifying or precluding factor loadings in advance.

SEM has also been credited with improving the rigor and complexity of empirical research. A researcher using SEM is more or less forced to develop a model. Because SEM has no default analyses, a researcher has to specify which relations between variables to compute and which ones are hypothesized to be nonexistent. The need to build a model prior to the analyses requires meticulous thinking about one's hypotheses concerning constructs and their interrelations (Hoyle, 1995). Such models can include so-called *indirect effects*. That is, an independent variable predicting an outcome variable—as in Beron and Farkas's (2004) study of oral language skill predicting reading success—can be a dependent variable at the same time and as such be predicted by a third variable, as oral language skill is predicted by race and parental education in Beron and Farkas (2004). With this feature, complex models can be designed to evaluate direct and indirect effects of, for example, background variables and learning condition variables on language performance. This kind of analysis can be done with observed variables (path models) when there is just one observed variable per theoretical variable, or at the level of the latent variables when multiple measures per theoretical variable have been included in the design to allow for model testing with "error-free" variables.

Using SEM to test a theoretical model is relatively new to applied linguistics; it has been used in recent studies of first and second language reading and writing proficiency (e.g., Abbott & Berninger, 1993; Schoonen et al., 2003; Van Gelderen et al., 2004; Phakiti, 2008). One of the earlier applications was to model the role of affective variables in language learning, as in Gardner's socioeducational model of L2 learning (Gardner, Tremblay, & Masgoret, 1997). Gardner and colleagues operationalized seven latent variables (by convention depicted as circles as in Figure 1) with a range of observed test and questionnaire scores (depicted as boxes). In this analysis (Gardner et al., 1997), Language Aptitude is measured by three (observed) variables (Spelling Clues, Words in Sentences and Paired Associates), and this part of the overall model is a measurement model. As is indicated by the factor loadings in Figure 1, Language Aptitude "explains" each of the observed scores to some degree (as indicated by the coefficients, .60, .69, and .35). All three measures are also affected by other effects (error), which is sometimes indicated by another arrow toward the observed score box (not shown in Figure 1). The latent variable based on these three observed variables can be considered *free of measurement error*, and thus regressions and correlations in the structural model are not affected (attenuated) by measurement error. In other cases, when there is just a single observed indicator for the latent variable, the latent and observed variable are equated to each other, as is the case for the theoretical variable Field Independence, measured by Group Embedded Figures (see Figure 1). In this latter case the advantage of error-free latent variables no longer holds.

The structural part of the model concerns the relationships between the latent variables, which can be directional as in regression analysis (single-headed arrows in Figure 1) or nondirectional as in correlation analysis (e.g., double-headed arrow between Field Independence and Language Aptitude in Figure 1). Gardner's model nicely illustrates the fact that some effects of (latent) variables can be mediated by other (latent) variables.

Figure 1 The causal model (Gardner et al., 1997, *Modern Language Journal*, 81 © Wiley-Blackwell)

For instance, Motivation has an indirect effect on Language Achievement that is mediated by Language Strategies, which has a direct effect on Language Achievement. At the same time Motivation also has a direct effect on Language Achievement. So, as was mentioned above, (latent) variables can be independent variables, that is, “predicting” other (latent) variables, or dependent variables, that is, being regressed on other variables, or both.

Variables that are regressed on other variables may still show an amount of “unexplained” variance. In Gardner’s model this is not indicated, but in other applications of SEM, it often is, again, by means of single-headed arrow toward the (latent) variable. In regression analysis, it would not have been possible to model direct and indirect effects and to test their existence, nor would it have been possible to work with “error-free,” latent variables. Estimates of correlations or regressions weights that are based on latent variables are not attenuated by unreliability of the measurements and as such provide a better indication of the actual strength of the relationships.

It is not difficult to imagine many more possible relationships between the seven latent variables in Gardner’s model. The flexibility in modeling these structural relationships is one of the strengths of SEM, but also one of its challenges. How can a researcher decide which model to choose?

Evaluation and Comparison of Models

The basic input of an SEM analysis is the covariance matrix of the observed variables, with the variables’ variances on the diagonal. The model specifies relations between observed and latent variables and between latent variables in terms of regressions, covariances, and variances. These parameters can be either free to be estimated, fixed at a certain value (typically zero), or constrained to be equal to another parameter. Based on these specifications a series of equations can be formulated with the specified model parameters on the one hand, and the observed (co)variances from the input matrix on the other hand. The model parameters are estimated such that a model-derived covariance matrix fits the observed matrix as closely as possible (Hershberger, Marcoulides, & Parramore, 2003). There are various criteria for minimization of the differences between the model-derived and the observed matrix, such as *maximum likelihood* and *generalized least squares* (Jöreskog & Sörbom, 1996; Kline, 2005; Ullman, 2007).

The ultimate selection of a model largely depends on its fit to the data. Researchers have many fit indices at their disposal and the evaluation of a model should be a weighing of the available indices that all have slightly different foci. First of all, there is a statistical evaluation of the model which tests whether or not the observed covariance matrix can be considered a sample matrix from the estimated population matrix. The difference between the two is expressed in a chi-square (χ^2) statistic with a corresponding degrees of freedom (df) and associated p -value. The χ^2 test is very sensitive to sample size, number of parameters in the model, and the degrees of freedom. In large samples, χ^2 is often statistically significant, which in this case means that the model has to be rejected because of the difference between the observed sample and the estimated population matrix, usually an undesired situation as SEM is essentially a confirmatory procedure. In these cases the χ^2 test might be misleading, as the statistical significance will largely be caused by a very high level of statistical power to detect small differences rather than serious misspecification in the model. Therefore, the ratio of χ^2 and df is often used as a more descriptive measure; χ^2/df preferably not exceeding 2 (Ullman, 2007).

Other frequently used, more descriptive measures are the comparative fit index (CFI), the root mean squared error of approximation (RMSEA), and the standardized root mean square of residual (SRMR). The CFI (like its related indices) is a so-called incremental fit index that indicates the relative improvement of the tested model over a baseline model, the so-called independence model. This latter model assumes that all variables are independent, that is, uncorrelated in the population (Kline, 2005). RMSEA is a fit index that indicates error in approximation. In doing so it corrects for model complexity and favors parsimony, taking sample size into account. The SRMR is directly related to the difference

between the observed standardized covariance matrix and the estimated standardized population matrix, that is, the correlation matrix and the reproduced correlation matrix. The SRMR is the mean (absolute) correlation residual. The fit of a model is considered acceptable when $CFI \geq .95$, $RMSEA \leq .06$, and $SRMR \leq .08$ (Hu & Bentler, 1999). However, we should bear in mind that the fit indices are general, overall measures that may not reflect local misspecification in a model. Therefore, it is highly important to review all the estimated parameters and to check their meaningfulness (Kline, 2005).

Researchers seldom test a single model. Often two or more competing models are compared, or modifications to an initial model are evaluated. In those cases a researcher can of course compare the aforementioned fit indices, but, as explained above, different fit indices foreground different aspects of a model. The difference between two models can be tested statistically when the models are nested, that is, when one model is a special case of the other, for example, because it has one or more free parameters fixed or constrained in comparison to the more general model. By definition, a more restrictive model will fit the data less well, but it is also more parsimonious and thus has more degrees of freedom. The difference in chi-square ($\Delta\chi^2$) with the corresponding difference in degrees of freedom (Δdf) is also chi-square distributed and therefore can be considered a statistical test for equal fit. If the chi-square difference test is not statistically significant, the more parsimonious model is to be preferred, because the fit has not changed significantly, despite the fixing or constraining of the parameter(s). The parameter(s) involved can be considered fixed or constrained. However, if the chi-square difference test is statistically significant for a particular model, its parameter(s) cannot be fixed or constrained without a significant decrease of fit (Kline, 2005; Ullman, 2007).

Comparing different models this way, Sawaki, Stricker, and Oranje (2009) tested several models that were to represent the factor structure of the Internet-based Test of English as a Foreign Language (TOEFL-iBT). The best-fitting model turned out to be one that consisted of four latent variables, one for each language skill—reading, listening, speaking, and writing—and a so-called higher order variable, ability in English as a second or foreign language (ESL/EFL), that represents the communality among those four latent variables. In another study, Song (2008) explores three subskills of reading and listening proficiency and the communalities of these subskills: understanding the main idea, understanding supporting details, and making inferences. Comparing models for one, two, or three subskills in each mode and a model that combines listening and reading subskills, Song showed that a three-factor model fits best for listening, and a two-factor model for reading. The subskills were not fully common across the two modes. Including two mode factors in the model, one for listening and one for reading, substantially improved model fit (Song, 2008). These complex relationships between variables could probably not be inferred from an inspection of the correlation matrix of the subskill scores, a multiple regression analysis, or a factor analysis.

Special Applications

Higher-Order Factors

Because SEM allows a researcher to model the relationships between (observed and latent) variables in a theoretically motivated way, higher-order factor analyses of, for instance, the hierarchical structure of intellectual abilities can be conducted (Chen & Michael, 1993). In language assessment, researchers have tested models of the hierarchical structure of speaking assessment data, that is, raters' ratings (observed scores) of task performances (first-order factor) and several task performances representing speaking proficiency (second-order factor) (see De Jong, Steinel, Florijn, Schoonen, & Hulstijn, *in press*). Sawaki et al.'s

(2009) study of the TOEFL-iBT also included a higher-order factor (i.e., ESL/EFL ability) in the final model.

Controlling for Variables

SEM also enables a researcher to investigate the covariance between two variables while controlling for a third one, that is, to study partial covariance (Preacher, 2006). In their study of L1 and EFL writing, Schoonen, Van Gelderen, Stoel, Hulstijn, and De Glopper (2011) tested lexical retrieval speed by having participants press the key of the initial letter of depicted words on a computer keyboard. This procedure confounds lexical retrieval and keyboard skills. However, keyboard skills were assessed separately and eventually partialled out from the correlation between lexical retrieval and writing proficiency; that is, this correlation was estimated *controlling* for keyboard fluency (Schoonen et al., 2011).

Analysis of Mean Structures

In structural equation models, the structure of mean scores of observed and latent variables can be modeled as well, and as such SEM allows for all kinds of ANOVA-like analyses. Rovine and Molenaar (2003) describe how to use SEM for conducting one-way ANOVAs, repeated measures ANOVAs, and mixed models. A special kind of analysis of the mean structures concerns the investigation of development or change in longitudinal studies. The growth of latent variables can be modeled as linear, quadratic, or otherwise. In general, these latent growth models (Duncan, Duncan, Strycker, Li, & Alpert, 1999; Kline, 2005; Ullman, 2007) presume two latent variables, one indicating the *intercept*, that is the initial level, and one indicating the *slope*, that is, the growth rate. These two latent variables reflect individual differences in initial level and growth rate, and thus individual growth curves. Stoel, Peetsma, and Roeleveld (2003) investigated children's language development in the school years in relation to their school investment and self-confidence. In their growth analysis, they found that the language development (i.e., the growth curve) was nonlinear and also that the growth rate of language ability was positively associated with the growth in self-confidence and with school investment. Growth rate is a latent variable that can be a dependent or independent variable in more complex models, as is illustrated by Stoel et al. (2003). See Ross (2005) for another example.

Multigroup Analysis

Models of relationships between variables and mean structures might hold for specific groups, such as L1 speakers, but possibly not for other groups, such as L2 speakers. These kinds of research questions can be addressed in SEM, using *multigroup analysis*. A multigroup analysis tests whether one and the same model is adequate for two or more different groups or samples. Researchers can also test hypotheses about specific parameters in different groups. Does the general structural model hold in all groups, allowing different estimates for regressions and other parameters? Or, more restrictively, is the model completely identical in the groups, that is, with the same structural and measurement model and identical parameter estimates? The researcher can fix parameters to be equal across groups in one run and release this constraint in a second run. Difference in model fit can be considered a test of the tenability of the equality hypothesis. For example, can we expect the constellation of constituent subskills of language proficiency to be the same for different groups of language learners? Van Gelderen et al. (2003) studied the components of English reading proficiency in students who learned English as an L2 compared to students who learned English as a third language (L3). These authors found that, despite differences in reading level and reliability of the measurements, the contributions of the different components skills to EFL reading proficiency were largely the same for the two groups.

Purpura (1998) studied strategy use in low-ability and high-ability groups of test takers and found, among other things, that relationships between strategy use and test performance are not equivalent across the two ability groups.

Comparing relations between latent variables across groups or within groups at different points in time presupposes that the researcher is dealing with the same latent variable. However, measurement models and their interpretations might differ across groups or over time. Therefore, it is recommended to test different degrees of *measurement invariance* (see Meredith, 1993) in advance. This means that restrictions on equal factor loadings, means, and residual variances are tested successively across the measurement models in different groups or at different points in time. Equal factor loadings and means are considered a prerequisite for meaningful comparisons. For an application, see Schoonen et al. (2011).

Assumptions and Cautionary Notes

SEM is typically used for the analysis of continuous interval data. The variances and covariances of the observed variables are compared with the variances and covariances estimated from the model parameters. Parameters are estimated such that the differences between the two variance-covariance matrices are minimized. This process of model fitting and evaluation entails a number of assumptions about data and the model (see Jöreskog & Sörbom, 1996; Hershberger et al., 2003). One is that the continuous variables show a multivariate normal distribution. When the data are highly non-normal, the χ^2 tends to be too large and other fit indices tend to be too low. In this case, the standard errors of the parameters will be underestimated (West, Finch, & Curran, 1995), possibly leading to the wrong interpretations and decisions. Different procedures are available to deal with non-normal continuous variables, such as transforming the non-normal data, as well as using adjusted fit indices, distribution-free estimation, and/or bootstrapping (West et al., 1995; Jöreskog & Sörbom, 1996; Kline, 2005). Special cases are ordinal data and categorical data. In those cases special precautions are needed to compute an appropriate covariance or correlation matrix as input data (Jöreskog & Sörbom, 1996; Kline, 2005; see also Rovine & Molenaar, 2003).

SEM can be deployed to test a theoretical model in a “strictly confirmatory” way (Jöreskog, 1993). Depending on the fit statistics the researcher will either reject or accept the model as correct. However, theories in the social sciences, including applied linguistics, are seldom sufficiently explicit to test one single model. Researchers are more likely to have two or more competing “alternative models” that are tested against the available data, or, even more likely, researchers only have general assumptions about the relationships between variables and they aim at “model generating” (Jöreskog, 1993, p. 295). In the latter situation, the model is modified after each run, that is, nonsignificant parameters are dropped and at other places parameters are included to optimize model fit. SEM software provides tools to evaluate the addition (i.e., modification indices or Lagrange multipliers) or deletion of parameters (i.e., Wald W statistic), making it easy to explore many models. However, with this procedure the researcher runs the risk of capitalizing on chance and of making more Type I errors than is desirable (see Green, Thompson, & Babyak, 1998). In search of maximum fit, researchers often allow for a covariance between measurement errors in models (so-called *correlated error*). Such a parameter (like all others) should have a theoretical underpinning, because it indicates that two variables are correlated more strongly than is represented by the general model. Such additional covariance implicitly refers to an additional factor or latent variable involved, such as the testing method used. In sum, the flexibility of SEM is a great asset, but also contains a risk of over-fitting. When using SEM and modifying models one should bear in mind that parameters, especially

paths (regressions) or covariances between (latent and/or observed) variables, or both, need to be theoretically meaningful (Hershberger et al., 2003). Furthermore, despite what the graphical representation with the one-way arrows suggests, SEM is an analytic tool based on covariances or correlations and therefore relations cannot be interpreted as being causal. Or as Ullman (2007, p. 682) puts it: "Attributing causality is a design issue, not a statistical issue."

Research in applied linguistics is likely to increasingly draw upon SEM because of the tools it provides for a range of sophisticated questions and hypothesis testing, most of which cannot be addressed with other analytic techniques. Complex models of relationships between numerous variables can be tested as one complex hypothesis. Furthermore, SEM can model unreliability of test scores and separate it from the substantive analyses of (latent) variables to test models. Perhaps most important, however, SEM prompts the researcher to model relations between variables a priori and thus to theorize about hypotheses.

Structural Equation Modeling in Language Assessment

YASUYO SAWAKI

Structural equation modeling (SEM) is a multivariate statistical technique used to examine underlying relationships among observed and latent (unobservable) variables. SEM takes a confirmatory approach to testing the degree to which a hypothesized model specified a priori fits data. SEM is typically used to examine covariance structures, namely, the pattern of covariation among a set of observed and latent variables. However, SEM is a flexible, overarching framework that can address various other types of research questions as well. For example, a type of SEM application called multiple-group analysis allows one to compare covariance structures as well as mean structures (mean performance levels) across groups. Moreover, growth modeling can be used to examine the pattern of growth, that is, performance changes on a set of variables of interest over time.

Previous SEM Applications in Language Assessment

In his overview article in the SEM special issue of *Language Testing*, Kunnan (1998) pointed out that the number of SEM applications in the field of language assessment was quite small at the time of his review. Since then, however, the number of SEM studies published in the field has been increasing steadily. Since Bachman and Palmer's (1981) first application of SEM to language assessment, SEM has been employed to address a variety of research questions. Some recent applications have focused, for example, on construct validation of language tests (e.g., Llosa, 2007; Sawaki, Stricker, & Oranje, 2009), empirical validation of substantive theories (e.g., Phakiti, 2008), exploration of the relationship between language test performance and learner characteristics (e.g., Purpura, 1999), and comparison of factor structures of language tests across heterogeneous groups of individuals (e.g., Shin, 2005; Stricker, Rock, & Lee, 2005). Moreover, Brindley and Ross (2001) offer a rare example of an application of growth modeling to language assessment. This entry focuses on basics of covariance structure analysis.

What Is an SEM Model?

SEM can be viewed as an extension of familiar statistical techniques such as regression analysis, path analysis, and factor analysis. A regression model defines direct predictive relationships among observed variables in a regression equation, where one or more variables serve as predictors of a criterion variable. Meanwhile, an SEM model defines both direct and indirect predictive relationships among a set of variables in a series of regression equations. While SEM is similar to path analysis in this sense, a notable advantage of SEM over path analysis is that one can test interrelationships among observed as well as latent variables that are unaffected by measurement error. Moreover, SEM subsumes factor analysis, as mentioned below.

In SEM two types of models are defined. One is a measurement model, which specifies predictive relationships between a latent variable and its indicators (observed variables).

Figure 1 A sample path diagram

The other is a structural model, which specifies predictive relationships among latent variables. A full SEM model comprises both measurement and structural models. A confirmatory factor analysis (CFA) model is a special type of SEM model that represents the measurement model only.

As an illustrative example, suppose that an investigator tests a hypothesis that second language (L2) learning motivation predicts listening and speaking abilities. Accordingly, the researcher administers an L2 learning motivation questionnaire as well as L2 listening and speaking tests to a group of learners. Suppose further that the survey and the two tests comprise four subtests each. Figure 1 is the path diagram for this example.

In a path diagram, by convention, a latent variable is represented by an oval, an observed variable by a rectangle, a regression path by a single-headed straight arrow, and a covariance between variables and residual variances (see Figure 1) by a double-headed curved arrow. The researcher hypothesizes that there are three latent variables that are related to one another (L2 listening and speaking abilities and L2 learning motivation) and that the subtests serve as indicators of the corresponding latent variables. Ellipsis A shows the part of the measurement model for L2 learning motivation. The single-headed arrows connecting the latent variable and its indicators denote regression paths, showing that L2 motivation predicts learners' subtest scores on the questionnaire. Moreover, the other set of single-headed arrows pointing at the observed variables represent residual variances, namely, the part of observed variances of the variables not explained by the latent variable.

Similarly, the left-hand portion of Figure 1 shows the part of the measurement model for listening and speaking. The structural model is denoted by Ellipsis B. The regression paths indicated by the single-headed straight arrows stemming from L2 motivation toward the other two latent variables show that L2 motivation predicts learners' listening and speaking abilities. The other set of single-headed straight arrows pointing at Listening and Speaking are residuals for these latent variables. Moreover, the covariance between the residual variances depicted by the double-headed arrow reflects the hypothesis that part of covariation between listening and speaking abilities is not explained by L2 motivation.

Three Approaches to SEM Applications

Jöreskog (1993) presents three approaches to SEM applications. The first is a strictly confirmatory approach, where a researcher specifies and empirically tests the goodness-of-fit of one and only one model. The second is testing alternative models, where a researcher compares relative goodness-of-fit of multiple SEM models offering alternative explanations about underlying relationships among observed and latent variables. The third is model generating, where a researcher specifies a tentative SEM model. Then, from empirical analysis results, he or she modifies parts of the initial model to develop a model that is substantively interpretable and fits the data well.

All these approaches have been used in previous language assessment studies in various ways. For instance, Phakiti's (2008) SEM study has a feature of the first approach because he tested only one SEM model depicting hypothesized interrelationships among knowledge about and use of strategies and reading test performance over time. Carr (2006) offers an example of the third approach. He generated SEM models that well represented interrelationships among test task characteristics and test performance on a reading comprehension test by discarding unnecessary variables and adding and dropping model parameters through testing a series of SEM models. The second type of applications plays an important role in construct validation of language tests in particular. This is because an important aspect of test validation is to explicitly reject plausible rival hypotheses. As an example of the second approach, Sawaki, Stricker, and Oranje (2009) compared multiple CFA models in a construct validation study of the TOEFL® Internet-Based Test (iBT). The TOEFL iBT™ test is designed to assess academic English as a second language/English as a foreign language (ESL/EFL) ability in the reading, listening, speaking, and writing modalities. Separate scores for these sections and a total score are reported to test users. Thus, by comparing the relative goodness-of-fit of competing CFA models, Sawaki et al. examined the degree to which the test was functioning as measures of the different constructs.

Figure 2 visually represents Sawaki et al.'s strategy. First, they identified a baseline model that reflects the basic test design comprising the four sections. Once they had confirmed a reasonable fit of this model to data, Sawaki et al. compared this model against the three alternative models that provided competing hypotheses to the underlying factor structure of the test. All the alternative models were more parsimonious than the baseline model. In other words, the alternative models involved fewer estimated model parameters than the baseline model. This approach was taken because a parsimonious model tends to replicate well in different samples. As the result, a higher-order factor model comprising four factors corresponding to the four modalities and a general factor underlying the four factors was identified as the final CFA model for the test form analyzed.

Steps Involved in an SEM Analysis

Six major steps involved in conducting an SEM analysis are summarized below. Further technical details about each step can be found in Jöreskog (1993), Kunnan (1998), Raykov and Marcoulides (2006), and Ullman (2007).

Step 1: Data Check

The appropriateness of data for SEM analysis is examined. Issues for consideration in this step include various statistical issues such as input data type (i.e., categorical vs. continuous data), sample size, presence of outliers, linearity of relationships among observed variables, and normality of score distribution. In particular, checking multivariate normality of data

Figure 2 CFA model comparison strategy employed by Sawaki et al. (2009)

Note. ESL/EFL = Academic ESL/EFL ability; Read = Reading ability; Listen = Listening ability; Write = Writing ability; Speak = Speaking ability; R/L/W = Reading, listening, and writing abilities

is essential because certain estimation methods (Step 4) assume multivariate normality. If this condition is not met, the data might be transformed. Alternatively, appropriate adjustments might be made when model fit is evaluated in Step 5.

Step 2: Model Specification

The next step is to specify an SEM model to be tested. As shown in the sample SEM model presented in Figure 1, decisions concerning how to specify predictive relationships among latent and observed variables are informed by substantive theory and previous empirical evidence.

Step 3: Model Identification

An SEM model is said to be identified when there is a unique solution for each model parameter being estimated. In order for this to happen, three conditions must be satisfied, although meeting them does not guarantee model identification. First, each latent factor must have a sufficient number of indicator variables. Second, the model degrees of freedom (*df*) must be positive. A positive model *df* results if $p(p+1)/2$, where p denotes the number of observed variables, is larger than the number of estimated model parameters. Third, the scale for each latent factor must be established. To achieve this, either the factor variance or a regression path for an indicator of the factor is fixed.

Step 4: Model Estimation

A mathematical function is fit to data in order to estimate model parameters. An appropriate estimator should be selected from among a variety of options by carefully considering various statistical issues such as data type, sample size, and normality of data.

Step 5: Testing Model Fit

Goodness-of-fit of a proposed SEM model to data is examined by evaluating how well the proposed model reproduces the observed covariance matrix. It is essential to evaluate model fit from multiple perspectives, including statistical and descriptive indices of overall model fit, residuals (discrepancy between observed and model-predicted covariance matrices), and substantive interpretability of model parameter estimates.

Step 6: Model Comparison/Modification

If multiple alternative models are compared, the relative goodness-of-fit of the models is compared from statistical and substantive perspectives. The same criteria as those considered in Step 5 are used for the comparisons. When two models being compared are nested with each other (i.e., when a model is a more parsimonious version of the other), a chi-square difference test can be used to statistically test the relative goodness-of-fit of the two models. Testing of an initial SEM model may be followed by model modification. A model modification process is guided by substantive theory, often with model modification indices. Such indices can be used, for instance, to identify model parameters that can be added to improve model fit and those that can be dropped without compromising model fit.

SEM Software

A range of statistical packages for conducting SEM analyses are currently available. Popular ones include AMOS, EQS, LISREL, and Mplus. While all of these have full capabilities to conduct SEM, their features differ slightly from one another. For a comparison of key features across different statistical packages, see Ullman (2007).

Writing About SEM Analysis Results

There has not yet been a clear consensus as to how to report SEM analysis results. For example, opinions as to which model fit indices to report vary across different SEM researchers. However, some references, such as Boomsma (2000), Hoyle and Panter (1995), and Ullman (2007), offer useful guidelines as to how to report SEM analysis results.

Study Abroad

JANE JACKSON

As a consequence of globalization and the push for internationalization on campuses across the globe, we are witnessing a dramatic increase in the number of students who are studying abroad. In 2006, the United Nations Educational, Scientific and Cultural Organization (UNESCO) estimated that there were more than 2.5 million students being educated at the tertiary level outside their home country, up from an estimated 1.7 million in 2000. By 2025, nearly 8 million students are expected to be educated transnationally (<http://atlas.iienetwork.org/>). While some join “year-abroad” or semester-long exchange programs, an even greater number are taking part in short-term sojourns, ranging from four to seven weeks, or micro-sojourns lasting three weeks or less (Spencer & Tuma, 2008). To facilitate comparisons of these programs, the Forum on Education Abroad (2009) published a glossary of terms used in North America, while Coleman (1997) provides insight into residence-abroad nomenclature in European contexts.

Students join study-abroad programs for diverse reasons. Some aim to enhance their foreign-language proficiency and gain firsthand exposure to elements of the host culture, as in the traditional “junior year-abroad” programs that were popular several decades ago. To fulfill a degree requirement in their home institution, students may take foreign-language courses at a commercial language center or university in the host culture. Not all students have language and cultural learning as their primary goal, however; some may focus on the acquisition of academic knowledge in other areas of study (e.g., architecture, engineering), others may aim to enhance their professional skills (e.g., business, health care) in another global context, and some may do both. Those with an advanced level of proficiency in the host language may study alongside host nationals in regular subject courses and then transfer credits to their home institution. Due to the emergence of English as the global language of internationalization, a growing number of non-English-speaking countries are now offering study-abroad students exposure to local (and global) course content through English.

Besides duration, aims, and medium of instruction, there are many other variations in study-abroad programs that may influence student learning, including housing options (e.g., homestays, residence in a dormitory, sharing an apartment with host nationals). Further, some programs may be faculty led, whereby an instructor or professor from the home institution accompanies a group abroad. A professor of French in the United States, for example, may travel to France with a group of students and teach French-language or cultural studies courses alongside local professors. In response to internationalization policies, institutions are also establishing exchange agreements with foreign counterparts, providing increased opportunities for students to venture abroad on their own.

The degree of pre-sojourn preparation, sojourn support, and reentry debriefing provided to study-abroad students also varies. It ranges from none at all to the integration of credit-bearing components into the undergraduate curriculum in the home institution (e.g., pre-sojourn, sojourn, post-sojourn coursework). Some institutions have developed an intensive predeparture orientation to address the challenges that sojourners may face in an unfamiliar sociocultural context (e.g., culture shock, language barriers, sociopragmatic differences, unfamiliar teaching styles).

2 STUDY ABROAD

The integration of ethnographic inquiry into study-abroad programming can help student sojourners become more systematic learners of language and culture and better prepared for life in the host speech community (e.g., Jurasek, Lamson, & O'Maley, 1996; Roberts, Byram, Barro, Jordan, & Street, 2001; Jackson, 2006; Ogden, 2006). In this experiential mode of learning, students are introduced to the aims and methods of ethnographic exploration: participant observation, note taking, interviewing/conversation techniques, and the use of visuals (e.g., digital photographs). With adequate support and preparation, students can develop the skills and confidence necessary to investigate a cultural scene in their home environment, reflect on their personal biases, and gradually move from description to analysis. In the host culture, they can then undertake an ethnographic project, which requires prolonged interpersonal contact across cultures and focuses attention on socio-cultural aspects of the host language.

Ethnography is not the only approach used to optimize study-abroad learning. At the Center for Advanced Research on Language Acquisition (CARLA) at the University of Minnesota in the United States, applied linguists have collaborated with intercultural educators to develop language and culture strategy materials to enhance the linguistic competence, sociopragmatic awareness, and intercultural communication skills of students on stays abroad (Cohen, Paige, Shively, Emert, & Hoff, 2005).

Ethnographic training and fieldwork (or other forms of experiential learning), and regular debriefing sessions during the sojourn can promote deep, critical reflection and accelerate language and (inter)cultural learning. To maximize and extend student learning, adequate post-sojourn debriefing is also important. While some institutions of higher education offer credit-bearing courses for returnees, the reality is that few provide this level of support.

Most language educators and students still assume that firsthand exposure to the native speech community along with formal classroom learning provides the best environment for learning an additional language and culture; however, is this necessarily the case? What actually happens when students study abroad? What do we know about language and culture learning in study-abroad programs? What does the research tell us?

Freed (1995) drew attention to second language acquisition research in study-abroad contexts, showcasing studies in the following areas: predicting and measuring language gains in the host culture; comparative investigations of language study at home and abroad; the acquisition of sociolinguistic competence in a study-abroad setting; and diary studies that centered on student perceptions of learning abroad. The majority of these studies addressed individual and group differences in linguistic outcomes (e.g., fluency, lexical and grammatical development, use of communication strategies). Although the findings were mixed, most lent support to the notion that study abroad can help learners become "fluent" speakers of the host language. When compared with foreign-language students who remain in their home environment, those who study abroad "appear to speak with greater ease and confidence, realized by a greater abundance of speech, spoken at a faster rate, and characterized, correspondingly, by fewer dysfluent-sounding silent and/or filler pauses" (Freed, 1995, p. 26). Freed (1995, p. 28) acknowledged that applied linguists have much to learn about "how students actually spend their time while abroad, which language they speak with friends and host families, the purposes for which and the amount of time they actually spend using the target language." Coleman (1997) also called for longitudinal studies that track the linguistic, affective, and cognitive development of student sojourners.

Collentine and Freed (2004, p. 157) warned study-abroad researchers that "focusing on traditional metrics of acquisition such as grammatical development might not capture important gains by learners whose learning is not limited to the formal classroom." Many large-scale, product-oriented studies have also been criticized for ignoring the sociocultural, political, and historical contexts of the learning situation. In response, a number of applied

linguists have been investigating the processes involved in language and (inter)cultural learning using introspective techniques (e.g., diaries, first-person narratives, interviews), and such approaches as case studies and ethnographies (Coleman, 2006; Kinginger, 2009). Qualitative researchers argue that an examination of the storied experiences of student sojourners helps elucidate what actually transpires on stays abroad.

In the first in-depth qualitative investigation of student migration within Europe, Murphy-Lejeune (2002) examined year-abroad students in three different programs: Erasmus (the European Region Action Scheme for the Mobility of University Students), bilateral language assistantships, and a French business-school program. Interview data revealed that the experience of mobility can transform students' concepts of "space" and "home" as they adjust to an unfamiliar environment and engage in new social scenes. Disorientation can also lead to an identity crisis.

Pellegrino (2005) investigated the self-presentation of American learners of Russian who participated in study-abroad programs in Russia. Several factors were found to inhibit their use of the host language, including anxiety, low self-esteem, and gender-related issues. Patron's (2007) investigation of French students on a year-long sojourn in Australia also drew attention to the impact of gendered identities on language learning. Through case studies of American undergraduates learning French in France, Kinginger (2008) raised further awareness of the complex interrelationship between motivation, identity, gender, language socialization, and culture learning.

Using an ethnographic approach, Jackson (2008, 2010) examined the language and (inter)cultural development of Chinese university students who participated in a short-term sojourn in England. While most enhanced their intercultural sensitivity and became much more confident when using the host language, their trajectories differed due to a range of factors (e.g., host receptivity, degree of investment in language and culture learning, personality attributes). As noted by Ryan (2003), "Residence in another country does not automatically produce interculturality." Knowing the grammar and vocabulary of the host language does not ensure intercultural communicative competence. Moreover, if students do not find their hosts welcoming, they may return home with negative stereotypes further entrenched.

More research in a variety of contexts is needed to better understand the multifarious internal and external elements that may foster or hinder language and culture learning on stays abroad. The findings can then provide direction for further enhancements in study-abroad programming.

Subjectivity

CLAIRE KRAMSCH

The feminist scholar Chris Weedon defines subjectivity as “the conscious and unconscious thoughts and emotions of the individual, her sense of herself and her ways of understanding her relation to the world” (1987, p. 32). This definition has been rephrased by Kramsch (2009) to underscore the symbolic nature of subjectivity as “our conscious or unconscious sense of self *as mediated through symbolic forms*” (p. 18, emphasis added). It is the symbolic meaning we give to ourselves, our perceptions, reactions, and thoughts, that orients our relationship to others. Subjectivity is produced discursively, that is, we are formed as subjects through the symbols we create, the chains of signification we construct, and the meanings we exchange with others. Subjectivity involves both the conscious mind and the unconscious body’s memories and fantasies, identifications, and projections.

This is not to say that the subject creates itself anew. Our subjectivity is constituted and shaped in interaction with our environment through the discourse of others—a subjectivity-in-process (Kristeva, 1986). We only learn who we are through the mirror of others; in turn, we only understand others by understanding ourselves as Other (Kristeva, 1991). The term subjectivity, then, does not mean narcissistic indulgence or arbitrariness and lack of objectivity, but, as Bakhtin (1986) would say, a responsibility to signify, use, and interpret signs, to respond to and “reaccentuate” signs, to pass judgment and take moral decisions. Thus subjectivity, inscribed in discourse, lies at the intersection of the individual and the social.

Language is the place where actual and possible forms of social organization and their likely social and political consequences are defined and contested. Yet it is also the place where our sense of ourselves, our subjectivity, is *constructed*. . . . Subjectivity is produced in a whole range of discursive practices—economic, social and political—the meanings of which are a constant site of struggle over power. (Weedon 1987, p. 21; emphasis in the original)

The Vocabulary of Subjectivity

Subjectivity has been of particular interest to feminist scholars within a poststructuralist tradition (Kristeva, 1986; Weedon, 1987; Butler, 1997; Threadgold, 1997), who have coined such notions as: subject, subjectivation, subject position, and intersubjectivity. The **subject** is distinct from the individual, the person, or even the self. The *individual* is usually taken to be a member of a group or collective community. It is a sociological or political entity that is guaranteed rights and obligations and has a certain social and cultural identity. The *person* is a moral, quasi-metaphysical entity whose integrity needs to be safeguarded and nurtured. The *self* is a psychological entity that is given to each human being at birth and is to be discovered, respected, and maintained. The *subject* is not given, but has to be consciously constructed against the backdrop of social and cultural forces that both bring it into being and threaten to destroy its freedom and autonomy. Subjectivity, as the creation and maintenance of a subject, emerges and develops through the use of symbolic forms like language, images, music (Deacon, 1997).

2 SUBJECTIVITY

Our ability to recognize and accept ourselves as subjects with emotions, feelings, memories, and desires is the prerequisite to developing our sense of self. In this sense, subjectivity is a process of **subjectivation** that feminists and poststructuralist critics call “decentering” (Threadgold, 1997, p. 5). It is a process in which the speaking subject as subject of enunciation strives to see itself and others in their full range of historical possibilities—hearing and seeing not only what they say and do, but what they could have said and done in the past, and what they could say and do in the future given the appropriate circumstances. One could say that becoming a subject means becoming aware of the gap between the words that people utter and the many meanings that these words could have, between the signifiers and the possible signifieds, between who one is and who one could be. This gap has been viewed by artists, philosophers, and feminist scholars as the very essence of life, change, and renewal.

The subject’s internal sense of coherence and continuity over time is socially constructed via the discourses and the idealized cognitive models (Lakoff, 1987) available in the community. It is the family, the school, the community that enable children to give meaning to their feelings, their experiences, their memories, in particular through language and through narratives of the self. The term **subject position** refers to the way in which the subject presents and represents itself discursively, psychologically, socially, and culturally through the use of symbolic systems. It comes from a view of the subject as decentered, historically and socially contingent upon its interaction with other contingent subjects. The many subject positions we take up during our lives sediment to form the historical, recognizable patterns that we call “identities.”

The term **intersubjectivity** is used with a different focus in discourse analysis and ethnomethodology on the one hand, and in poststructuralist feminist linguistics on the other. Discourse analysts and ethnomethodologists who study language as social interaction define intersubjectivity as a social accomplishment through the structural features of conversation. In this discourse analytic tradition, intersubjectivity is achieved on the basis of how participants orient to one another and to the here-and-now context of an interaction. When used by poststructuralist scholars, the term intersubjectivity goes beyond what is achieved in daily encounters between speakers. It is to be found in the shared memories, connotations, projections, inferences elicited by the various sign systems we use in concert with others. In this sense intersubjectivity is synonymous with intertextuality—*text* standing for any stretch of discourse, in whatever modality, produced at whatever point in time and in whatever place. What poststructuralist approaches to subjectivity add to the social interactionist approach is a symbolic and an historical dimension. What people say is both more and less than they intend to say. Bakhtin’s notion of *addressivity* (1986, p. 95) captures the fact that any utterance is a response to past utterances by now living or no longer living individuals, and that it addresses, or calls for a response from, others.

Poststructuralist Perspectives

Given Weedon’s poststructuralist orientation, based on Foucault (1970), Althusser (1971), Kristeva (1986), and other feminist thinkers, and her interest in avoiding the essentialism of identity politics, it is not surprising that she speaks of “subject positions” rather than identity. Subject positions are taken up in discourse, they are ways of making meaning that are contingent on the social, moral, and ideological conditions of possibility afforded at the moment. Poststructuralist thought views the subject as both constructing and constructed by (subjected to) larger discourses, or regimes of meaning, which are realized, though not exclusively, through language:

The individual is both the site for a range of possible forms of subjectivity and, at any particular moment of thought or speech, a subject, subjected to the regime of meaning of a particular discourse and enabled to act accordingly. The position of subject, from which language is articulated and from which speech acts, thoughts or writing appear to originate, is integral to the structure of language, and, by extension, to the structure of the conscious subjectivity which it constitutes. (Weedon, 1987, p. 34)

In the same manner as the structure of the language we use constrains, but does not determine, what we can say, the structure of acceptable discourses in the time and place that we occupy constrains, without dictating, who we can be. Such a view is called “post-structuralist” because it rejects any fixed, unitary meaning attached to the structure of the linguistic sign and it highlights the power struggles that surround the making and organizing of meaning. For example, the sign “woman” can be interpreted in many different ways depending on how you choose to position yourself as speaking subject; it is not dictated by biology or social convention, even though there are dominant discourses that seek to make such subject positions into fixed and stable identities. Scholars of subjectivity underscore the power that subjects have to resignify dominant discourses and thus to subvert the established order. Referring to hate speech and the injurious use of terms like “queer,” Butler writes: “Speech is not only defined by social context, it is also marked by its capacity to break with context” (1997, p. 40). “As we think about worlds that might one day become thinkable, sayable, legible . . . the resignification of speech requires opening new contexts, speaking in ways that have never been legitimated, and hence producing legitimation in new and future forms” (p. 41).

Subjectivity in Second Language Acquisition (SLA)

The sociocultural turn in SLA research of the last 20 years (Block, 2003) has been accompanied by what one could call an inward turn. Researchers are keen to explore the construction and reconstruction of social identities (Norton, 2000) or “selves” (Pavlenko & Lantolf, 2000) through membership in social communities that cut across institutional lines and lay a claim to “social spaces and prerogatives” (Pavlenko, 2005, p. 197). At the same time, they have turned their attention to the emotional (Pavlenko, 2005; Dewaele, 2010), subjective experiences of L2 learners (Kinging, 2004; Kramsch, 2009). The recent proliferation in the book market of language memoirs, autobiographical testimonies, immigrant life stories, and other confessional accounts of bilingual experience, written by bilingual writers in their L2, has offered fascinating insights into the subjective aspects of SLA. They have provided ample data that require new modes of analysis and interpretation. They confront applied linguists with their cross-disciplinary position between the social and the human sciences.

The *coup d'envoi* to an exploration of subjectivity in SLA was given by Bonny Norton Peirce (Peirce, 1995), who was the first to put identity and subjectivity on the agenda of SLA research. In her influential longitudinal study of five immigrant women in Canada, she described in detail through participants’ diaries and interviews over a six-month period the difficulties these women had in acquiring English and the changes in social identity they experienced. Their struggles were less with the English language itself than with the identity they were forced to take as helpless immigrants at the bottom of the totem pole. Their motivation to learn the language was recast as *investment*—a “learner’s commitment to learning an L2, which is viewed as related to the social identities they construct for themselves as learners” (Ellis, 1997, cited in Norton, 2000, p. 11). For Norton, investment is different from instrumental motivation inasmuch as it requires the learners to “constantly

4 SUBJECTIVITY

organize and reorganize a sense of who they are and how they relate to the social world" (p. 11). Drawing on Pierre Bourdieu's economic metaphors, in particular his notion of cultural capital, Norton describes how learners "invest" in the second language and "expect good return on that investment" (p. 11). At the same time, inspired by Weedon's feminist and poststructuralist theory, Norton insists that "a learner's investment in the target language may be complex, contradictory and in a state of flux" (p. 11). Since an investment in the target language is also an investment in a learner's own identity, this identity, she writes, is "constantly changing across time and space" (p. 11). Norton's study has been influential in featuring language learners as having complex, multiple, and conflictual identities which they draw on to find appropriate "subject positions" in the new communities they are seeking to belong to.

However, while Norton, Pavlenko, and other applied linguists have drawn on Weedon's work to argue for educational equity and social justice, especially for immigrant learners of English, their use of the terms identity and subjectivity has resulted in some confusion in applied linguistics (for a review, see Block, 2008, pp. 217–18). Because of their close alignment with Vygotskian sociocultural theory and collaborative learning theories, they have conflated identity and subject position and "converted subjectivities, as it were, into more stable identities" (Block, 2008, pp. 217–18). Weedon was clear about locating subjectivity in discourse in the sociohistorical, Foucauldian sense of "modes of thought" in a given period of history. She writes:

Discourse is a structuring principle of society, in social institutions, modes of thought and individual subjectivity . . . Meanings do not exist prior to their articulation in language and language is not an abstract system, but is always socially and historically located in discourses. Discourses represent political interests and in consequence are constantly vying for status and power. *The site of this battle for power is the subjectivity of the individual and it is a battle in which the individual is an active but not sovereign protagonist.* (Weedon, 1987, p. 41, emphasis added)

The difference between agency and sovereignty is crucial to understanding the inherent tension between an individual's subjectivity and the identity options given to him or her by the group. This tension creates the conditions of possibility in which the speaking subject may be heard and listened to. The struggle about subjectivity is not about which social identity will be acknowledged and accepted (e.g., woman, mother, gay, immigrant, etc.), but which kinds of concepts may be thought at all (e.g., women's rights and gay marriage in Islamic societies; communist ideals in capitalistic societies). As Pennycook writes:

[In a Foucauldian sense] discourse does not refer to language or uses of language, but to ways of organizing meaning that are often, though not exclusively, realized through language. Discourses are about the creation and limitation of possibilities, they are systems of power/knowledge (*pouvoir/savoir*) within which we take up subject positions. (Pennycook, 1994, p. 128)

Because the poststructuralist position on subjectivity views power as plural and relational, it has been accused of "leading to pluralism and relativism and ultimately to individualist politics" (Weedon, 1987, p. 178). Weedon is keenly aware of the relations of oppression produced and reproduced in discourse, but, like other feminist theorists (e.g., Kristeva, Butler), she does not believe theories of oppression have an external guarantee of absolute "truth" or "reality." Rather, "they have a strategic status, depending on the specific discursive power relations in play" (p. 180). In other words, the purpose of poststructuralist theory is to problematize the very categories offered by dominant discourses, such as

“man,” “woman,” “community,” or “identity,” and to explore which subject positions are strategically possible and which are impossible in a given time and place. A focus on subjectivity does not mean abandoning the possibility of social change, it only means questioning the ideological and historical basis of the various discourses at hand and defining one’s subject position case by case. Despite Weedon’s clarifications, the poststructuralist position has not been adopted as intended by those who are keen to empower immigrants in English-dominant societies. Applied linguists who, like Norton and Pavlenko, have recast Weedon’s feminist theory of subjectivity into a theory of identity in SLA are now joined by researchers like McNamara (2010), who find in poststructuralism fruitful avenues for research and teaching practice in applied linguistics.

Research Methodology

The current debate about the poststructuralist use of the term “subjectivity” raises the question of the application of SLA research to language teaching and learning. Is the goal to help learners find the best possible social identity in order to claim social spaces and prerogatives? Or is it to understand the conditions of possibility of appropriating both the forms and the use of the language in unequal discursive practices and historical settings? In short, is SLA research meant to help *prescribe and predict* the success of various pedagogic interventions or to *describe and document* the ecological complexity of the SLA process?

In applied linguistics, subjectivity has been studied through ethnographic approaches such as published language memoirs, life stories, and other autobiographical testimonies (e.g., Pavlenko, 2001; Kinginger, 2004, 2009; Kramsch, 2009) which have called for a mode of analysis that is more akin to literary interpretation than to sociolinguistic analysis. Identity and subjectivity illuminate two different but complementary aspects of the self and two different emphases placed on representatives of the “symbolic species” (Deacon, 1997). These can be seen either as members of a community (identity) or as makers of meaning through the use of symbols (subjectivity). Between statistical surveys and qualitative ethnographies, Bourdieu (2003), who would not want to be included among the poststructuralists, has offered a third reflexive mode of analysis which he called “participant objectivation,” and which is finding resonance among sociolinguists. This mode of analysis eschews both the facile narcissism of researchers’ self-disclosure and the positivistic stance taken by social scientists who discard all subjectivity in their search for objectivity. By exploring the personal, political, social, and cultural conditions of possibility of their own research questions, researchers objectivate their own participation in the research project and give new meaning to the notion of subjectivity in applied linguistics.

Suprasegmentals: Discourse Intonation

LUCY PICKERING

Intonation is narrowly defined as the linguistically significant use of pitch movement at the suprasegmental level. This contrasts intonation with *tone*, which refers to the systematic use of pitch at the lexical level as seen in languages such as Chinese. A broader definition of intonation, often used for pedagogical purposes, includes intonation group analysis, that is, the alignment of the pitch contour with phrasal or clausal groups separated by pauses.

The intonation system in English performs multiple functions (Tench, 1996). Analyses in the first half of the 20th century ascribed primarily attitudinal and grammatical functions to intonational contours; more recently, however, prompted by a consideration of the cohesive devices underlying entire spoken texts, a principally textual or discourse function has been identified. Studies suggest that speakers signal topic structure by using pitch height and pause length to mark boundary strength. Listeners are also able to identify major discourse boundaries and predict when an utterance is likely to end using only features such as pause length and pitch variation (Cutler, Dahan, & van Donselaar, 1997).

In addition to this informational function, intonation plays an important role in successfully maintaining conversational involvement (Couper-Kuhlen & Selting, 1996). Systematic conventions of pitch variation are used to communicate understanding of status differences between interlocutors and project speaker assumptions regarding what information is new or shared in the context of a specific interaction (Brazil, 1985/1997). Thus, intonation bears a high communicative load in terms of both structuring information and expressing relationships between discourse participants, and forges a natural link between linguistic and sociolinguistic aspects of language (Gumperz, 1982).

The term *discourse intonation* is currently used to refer both in general terms to the discourse functions of intonation described above (Chun, 2002) and more specifically to the model of discourse intonation proposed by David Brazil (1985/1997) in his work on the English intonation system.

Brazil's model has become influential in British and Asian contexts and to a lesser extent in the United States. It has been applied to both native varieties and World Englishes (e.g., Cheng, Greaves, & Warren, 2008) and to second language (L2) varieties of English (e.g., Hewings, 1995). Unlike earlier models of intonational meaning (e.g., Halliday, 1967) which proposed that intonational primitives were coextensive with information units, syntactic clauses, or both, Brazil's builds an independent system based on phonological form which assigns a primarily pragmatic function to intonation choices. In this model, intonational structure contributes directly to a negotiation of a *state of convergence*, or informational or social confluence between interlocutors. Pragmatic intent is understood by speaker-hearers of the same community based on their shared set of sociocultural and linguistic experiences, which allow interlocutors to comfortably maintain interactional involvement. In common with Pierrehumbert and Hirschberg's (1990) model of intonational meaning based on American English, Brazil proposes a componential model in which meaning is conveyed by specific components of the contour rather than the shape of the contour as a whole. The four systems that comprise Brazil's system—the tonic segment, key choice, termination choice and tone choice—are summarized in Figure 1 and described in detail below.

2 SUPRASEGMENTALS: DISCOURSE INTONATION

Figure 1 Model of discourse intonation (adapted from Brazil, 1985/1997)

Tone Unit and Tonic Segment

Stretches of spoken discourse are divided into pitch-defined *tone units* which may also coincide with non-pitch-related phenomena such as pause units. Within each tone unit *prominent* or stressed syllables define the tonic segment of the unit, that is, the part of the unit comprising linguistically significant pitch choices. The speaker assigns prominence based on their assessment of the current understanding of the hearer(s). In (1)–(3), adapted from Brazil (1997, pp. 22–3), prominent syllables (shown in capital letters) co-occur with the (R)esponder’s understanding of the new information that the (Q)uestioner is seeking in each specific case:

- (1) Q: What card did you play?
R: //the KING of SPADES// (both the kind of face card and the suit are new information)

- (2) Q: What spade did you play?
 R: //the KING of spades// (only the kind of face card is new information)
- (3) Q: Which king did you play?
 R: //the king of SPADES// (only the suit is new information)

Typically, a tone unit will comprise two prominent syllables, an *onset* and a *tonic syllable*, which are the sites for significant pitch choices within two systems of pitch level (*key* and *termination* choice) and a system of pitch movement (*tone* choice.) These three interlocking systems form the basic components of the intonation system in English and have independent implications for the communicative value of the discourse.

Key and Termination Systems

The two systems of key and termination are concerned with pitch level. They operate in conjunction with the tonal system and play an important role in the local management of turn-taking structure and inter-speaker cooperation. Key choice is realized on the onset syllable (the first prominent syllable in the tone unit) and termination choice on the tonic syllable. In cases where there is only one prominent syllable in the tone unit, both key and termination choice fall on the same syllable, as shown in the examples below. Using the voice range of the speaker as a “minimally fixed framework” (Couper-Kuhlen, 1986), the first onset key is identified as either high, mid, or low. Subsequent termination levels are identified as appreciably “higher than” or “lower than” the preceding key choice. Each of the pitch level choices carries a specific pragmatic value.

Choice of high key or termination on a prominent syllable denotes the constituent (or matter of the tone unit) as either *contrastive* or *particularized*, that is, highlighted as crucial over and above the surrounding information:

- (4) FAILED//
 //he took the exAM// and
 He did not pass, as you might have expected: contrastive. (Sinclair & Brazil, 1982, p. 144)

Mid key choices have an additive function and denote the constituent as an *expansion* or *enlargement* of the information in previous units:

- (5) //he took the exAM// and FAILED//
 He did both: additive. (Sinclair & Brazil, 1982, p. 144)

A mid-level termination choice carries an expectation that the hearer will concur with the utterance. In conversational exchanges, it is essentially the unmarked key and termination choice.

Finally, a low key choice signifies an *equative* value in relation to previous units; that is, the information will match any previous expectations held by the hearer:

- (6) //he took the exAM// and
 FAILED//
 As you would expect; from what you know of him you will assume that taking it involves failing it: equative. (Sinclair & Brazil, 1982, p. 144)

4 SUPRASEGMENTALS: DISCOURSE INTONATION

In exchange structure, a low termination choice carries an additional restrictive function as it indicates the completion of the exchange. This is particularly evident in interactions between participants of unequal status where it is the prerogative of the participant with the higher status to signal the end of the exchange, as we see in typical teacher–student (T–S) interactional exchange units:

- (7)
- T: M H
 L //where do we get TEA from//
- S: M H
 L //CHIna//
- T: M H
 L //CHIna//
 //GOOD//

Tone System

The tone system is concerned with pitch movement rather than pitch level. Tone choice describes the choice of a rising (both rising and falling-rising), falling (both falling and rising-falling), or level pitch movement on the tonic syllable or nucleus of the tone unit, that is, the last prominent syllable in the tone unit. Tone selection marks both the informational status of the utterance and its social significance within the context of the interaction and is chosen by the speaker based on her understanding of the background knowledge of the hearer. Falling tones ([↘] and [↘↗]) indicate the speaker's assumptions that the propositional content of the tone unit is a new assertion in relation to the hearer, that is, in some way changing the state of the hearer's current understanding or unrecoverable from the context. Rising tones ([↗] and [↗↘]) indicate that the speaker assumes this information is part of the shared background between participants and agrees with the current worldview of the hearer. This shared information may be recoverable from the preceding discourse or prior knowledge assumed by the speaker to be common ground at that time. This is demonstrated in (8), adapted from Brazil (1997, p. 68), in which (8a) assumes that the common ground is Benjamin Jones, and (8b) assumes that the common ground is his profession (tone choice is underlined):

- (8) a. //↗BENjamin JONES// ↘is a DOCTOR// 'talking of Benjamin Jones, he's a doctor'
 b. //↘BENjamin JONES// ↗is a DOCTOR// 'talking of doctors, Benjamin Jones is one'

The notion of inclusiveness inherent in a rising tone choice is also apparent in interactional exchanges in which speakers wish to project a broader common ground in order to decrease the affective distance between themselves and their hearers; for example, the use of a rising tone rather than a falling tone when contradicting a previous speaker in order to avoid the appearance of overt disagreement (Hewings, 1995). In (9), adapted from Pickering (2001, p. 244), a chemistry teacher uses this strategy to indicate that a student has incorrectly responded to his question:

- (9) T: //How do we test for that compound specifically?//
 S: //We heat it//
 T: //↗WELL// if you remember that didn't ↗WORK too well//

The last of the five tones, the level tone choice (➔), is marked as communicatively neutral and presents the utterance as neither shared nor new but simply a language specimen. By placing the utterance outside of the context expressed in the other parts of the discourse message, the speaker can signal a suspension of the moment-by-moment negotiation for any number of reasons related to the social or informational aspects of the interaction. Brazil suggests that the level tone is most commonly used in two situations. The first is in semi-ritualized or routinized language behavior such as choral prayer or giving directives in the classroom: //➔ stop WRITing// ➔PUT your PENS down// (Brazil, 1997, p. 138). An utterance presented in this manner can be glossed as “these are not my words addressed particularly to you on this occasion; they are rather a routine performance whose appropriateness to our present situation we both recognize” (Brazil, 1997, p. 136). The second is in places where the speaker may have momentary problems with linguistic coding. For example, unplanned discourse is often filled with pause fillers and other kinds of hesitation markers, which will frequently be uttered in a level tone. Level tones may also occur when the speaker is unfamiliar with the language itself, as may happen with non-native speakers of English or when young children read aloud. In both cases, decisions in the intonation system may be made on the basis of the linguistic organization of the text rather than of concern for how any given utterance meshes with the context of the interaction for the benefit of the hearer.

It should be emphasized that with regard to all of these systems—prominence, tone, key, and termination—there is no absolute requirement that a speaker must obey the expected constraints. Rather, the intonation systems operate on the premise that, generally speaking, a speaker’s contributions are designed to be understood. From this, we assume that speakers will assess the state of convergence between themselves, the hearer, and the message. However, it is also important to remember that speaker intention can override any expected choices that may be anticipated based on context.

A significant innovation in Brazil’s model is the inclusion of the relative pitch onset level at the left edge of the tonic segment (realized on the onset syllable.) From this, two additional pitch regularities that appear in spoken discourse can be derived: the pitch sequence and pitch concord.

Pitch Sequence and Pitch Concord

The inclusion in the model of key choice, or relative pitch onset level, provides a principled framework for the description and interpretation of a prosodic unit larger than the tone unit: a *pitch sequence*. These intonational paragraphs are also described as *paratones* or speech paragraphs in the literature (Wennerstrom, 2001). A pitch sequence comprises a stretch of consecutive tone units that fall between two low termination choices. Prominent phonetic boundary cues include a high key onset with increased volume and rate, and a low termination possibly accompanied by laryngealization, a drop in volume, and narrowing of the pitch range. In addition to the boundary criteria, there is typically a gradual descent in pitch across the unit, usually referred to as *declination*. A pitch sequence may be uttered by one speaker or shared between two participants in an exchange. It typically delimits longer sections of speech and may be related, in terms of communicative value, to the next or previous pitch sequence or the consistent tone units within it.

Brazil also proposes a mechanism of *pitch concord*, which describes pitch range interactions between speakers. In exchanges, following the introduction of a new range of pitch norms, a second speaker may aim to match an initial key choice to the final termination choice of the first speaker; that is, a high termination from the first speaker will “invite” a second speaker to produce a similar high onset pitch. This is also described in the literature as *prosodic matching* (Szczepek Reed, 2006).

As with any linguistic system, intonational choices are conventionalized and contextually meaningful in discourse. Recognition of overall *prosodic composition* (Tench, 1996) is one way in which we identify different language events; for example, we are hearing classroom discourse as opposed to hearing the news on the television or radio. Brazil's model of discourse intonation enables us to explore precisely how we understand these choices both for pedagogical (see, for example, Bradford, 1988, and Cauldwell, 2003) and analytical purposes.

Suprasegmentals: Intonation

JOHN LEVIS

Intonation

Intonation refers to a combination of acoustic parameters, including duration, intensity, and pitch used to communicate discourse meaning. It is different from tone, the systematic use of voice pitch to distinguish lexical items. The most important parameter, pitch, is determined by the fundamental frequency, or F0, of speech, and is measured in hertz (Hz) or semitones. F0 can only be measured during voiced intervals because voiceless segments have no F0, and thus leave a gap in the measurement of pitch, as in the beginning segment of the word *fine* in the sentence in Figure 1 (marked by the arrow). Lack of measureable F0 may also occur because of other features of the speech signal such as excessive creaky voice or insufficient loudness.

Ladd (2008) diagrams the relationship between the two clearest types of intonational meaning in English, relative prominence and tune (Figure 2). As an answer to the question, “How much did it cost?” the falling tune in (a) is a straightforward reply, while the rising tune in (b) communicates uncertainty or questioning. The different prominence patterns (or tonicity) in (c) and (d) occur in very different discourse contexts because they single out FIVE for special attention. If someone asks, “Did you say it cost nine pounds?” the

Figure 1 Fundamental frequency (F0) of the sentence *Ann needs a fine-grained one* (using SFS/WASP speech analysis software)

Figure 2 Tune and relative prominence in English

answer in (c) can be given, while (d) is used to combine uncertainty and the special attention to FIVE, as in “Did it cost FIVE pounds? FIVE pounds? I’m not sure.” Regardless of the discourse context, two distinct uses of pitch are represented, one at the end of utterances, the other marking particular syllables as prominent.

Describing Intonation

According to Ladd (1980), “our first task in analyzing intonation must be to identify the inventory of meaningful elements” (p. 14). However, there are significant disagreements in applied linguistics about the linguistic categories of intonation and how they can be mapped onto the phonetic reality of continuous pitch movement. The inventories of meaningful elements vary according to language, with various ways to describe these elements even for the same language (Hirst & DeCristo, 1998).

Until the 1970s, intonation was largely described impressionistically. Today, all serious claims about intonation are subject to instrumental measurement. However, this shift in approach has not settled the debate over whether intonation is best described as static (that is, made up of level tones) or dynamic (made up of moving tones).

Straddling these two dominant approaches with a unique approach to description was Dwight Bolinger, who wrote from the 1950s to around 1990. Bolinger highlighted the importance of pitch accents, which continue to be central in all descriptions of intonation. He defined these in terms of the pitch movement used to accent syllables. Thus, “the pitch does two things at once. First, it signals an accent on that syllable. Second, its direction—up, down, or level—contributes to the melody” (Bolinger, 1986, 24). Bolinger’s influence on intonation has been substantial, but his intonational description is rarely referred to in applied linguistics.

Historically (when looking at descriptions of English), a major disagreement in applied linguistics descriptions has been whether intonation’s atomic components should be represented as static or dynamic, that is, whether pitch contours are comprised of pitch levels or are better seen as holistic configurations. In descriptions of English intonation, the pitch level approach has been favored by Americans, while the configurations approach has been favored by British applied linguists. The two approaches have long used different notation schemes, whose descriptions largely address many of the same issues. The traditional American levels approach has always built into meaningful configurations, while the British configurations approach has always included more basic elements that make up the configurations. Nonetheless, it is useful to understand the historical evolution of the two approaches, if only because their formalism remains a powerful mask to underlying similarities.

Figure 3 Pike's four-level system of intonation

The Levels Approach

The levels approach was pioneered by Pike (1945) who posited four phonemic (or tonemic) pitch levels for American English (Figure 3).

In this approach, intonation is defined in relation to the stressed syllables of speech, similar to Bolinger's notion of pitch accent, an insight essential to modern accounts. (See Liberman, 1978, for another treatment.) Stressed syllables start each contour, and an utterance can have multiple contours. Pitch levels 2 and 3 are the norm for the voice, with level 1 used for strong emotion or attitudinal meaning, and level 4 used primarily for endings. The two falling contours in Figure 3 are described as $^{\circ}1-4$ and $^{\circ}3-2-4$. The beginning of each contour is the stressed syllable, and the end is the final point before the next contour begins. In Pike's system, it is possible to have multiple, meaningfully distinct contours of the same general shape, e.g., $^{\circ}1-4$, $^{\circ}2-4$, $^{\circ}3-4$, $^{\circ}2-3$, $^{\circ}1-3$, and $^{\circ}1-2$ are all falling contours, each with a different attitudinal meaning.

Pike's formalism was originally meant as both theoretical description (the four levels were based on English but were thought to be universal) as well as an applied approach to teach foreign learners of English. Although four levels are no longer used for describing English intonation, having been replaced by the two-level approach of Pierrehumbert (1980), four levels are still widely used in applied materials for teaching English (Celce-Murcia, Brinton, & Goodwin, 2010). After Pike, various researchers used the four-level system, some with 1 representing the highest level and some with 4, and the actual connection of numbers to pitches was flexible. Today, the standard in pronunciation teaching materials has the highest pitch as level 4 and the lowest as level 1.

Pike's approach had flaws, most critical being the system's descriptive overgeneration of contours with little clear difference in meaning. If two contours were phonetically distinct, they were assumed to also be meaningfully distinct. For example, the $^{\circ}2-4$ and $^{\circ}3-4$ contours were both falling and considered different contours with related meanings. Pike himself recognized a potential difficulty, saying that contours that were similar in form (such as the falling contours) shared common abstract meanings, in this case, the meaning of "CONTRASTIVE POINTING" (Pike's emphasis, 1945, p. 44).

The levels approach pioneered by Pike was revisited by Liberman (1978), reflecting renewed interest in intonational description, meaning (Ladd, 1980), and specialized contours (Bing, 1980). Research on pitch accent in Swedish (e.g., Bruce, 1983) was applied by Pierrehumbert (1980) to the description of English intonation, providing a principled account of both phonetic accuracy and phonemic distinctiveness as well as the connections between underlying tonal structure and the phonetic shape of utterances.

Pierrehumbert's account also broke new ground in that it relied on instrumental measurements rather than impressionistic description. She argued that H and L tones operated in three different discourse domains: the pitch accent (at least one in each spoken phrase, marked with the diacritic *), the end of the intermediate phrase (the phrasal tone, marked with -), and the end of the intonational phrase (the final boundary tone, marked with %). The combination of H and L tones therefore make up the contour, such as $H^* L- H\%$, or a falling-rising contour.

Pierrehumbert's account of pitch accents also accounted for the alignment of the pitch accent to rhythmic structure via the placement of the stressed syllable, such that there were six possible pitch accents in English (H^* , L^* , L^*+H , H^*+L , $L+H^*$, $H+L^*$). In each of the complex pitch accents, the stressed syllable is aligned with the $*$, and the pitch movement occurs either before or after the stressed syllable.

Pierrehumbert's system is now dominant in theoretical and laboratory accounts of intonation (see Ladd, 2008) and has been codified into the ToBI system ("Tones and Break Indices") (<http://www.ling.ohio-state.edu/~tobi/>) for laboratory investigations in a wide variety of languages. Investigations using ToBI have led to a variety of modifications to the original system depending on the languages being investigated. However, the system is rarely used in applied linguistics research (e.g., Wennerstrom, 1998; Levis, 2002) and pedagogical materials. This divide between linguistic and applied linguistic accounts of intonation means that applied linguistics as a field rarely shows awareness of this significant body of research.

The Configuration Approach

The other major descriptive approach to intonation can be seen in the British tunes approach, sometimes called the configuration approach by Bolinger (see Ladd, 1980). Although the configuration approach also includes smaller elements, as in the levels approach, intonation contours are more often treated as unified wholes, and the overall tunes are treated as meaningful units of the intonational system. (It can also be argued that the levels approach included overall tunes, but the impression is that the levels were more important than the tunes.)

In British accounts of intonation, sentence-final contours are often called "nuclear tones" (e.g., Cruttenden, 1997) in that they include both the nucleus (or prominent syllable) and the following pitch movement. Thus a falling nuclear tone would include a prominent jump in pitch on BEST (the nucleus) and a falling pitch to the end of the utterance. Nuclear tones are typically marked with shorthand diacritics (e.g., $\overset{\sim}{\sim}$ for falling, high rising, falling-rising, etc.), a system first used by Harold Palmer in 1922 and codified by Roger Kingdon in 1958 (Ladd, 1980).

- (1) A: Is that your friend?
B: He's my very $\overset{\sim}{\sim}$ BEST friend.

Intonation thus involves, besides other acoustic features, meaningful pitch in several domains. Halliday (1967) calls the primary domains *tone*, *tonality*, and *tonicity*. Tone (elsewhere and more commonly called *tune*) is intonation to communicate meaning at the end of a sentence. Thus the choice of rising versus falling in the utterance *He's ready* is an example of a tone choice. Tonality divides spoken phrases, as in the sentence *If you leave now, don't come back*. Third, tonicity is the use of pitch to single out a word or syllable as informationally prominent, as in *HE'S ready* versus *He's READy*. It also may include significant uses of pitch range called KEY (Brazil, 1997).

An extensive treatment of intonation from this approach was O'Connor and Arnold (1961), a work equivalent in scope to Pike's description of American English. (Like Pike, they also wrote to teach intonation to foreign learners of English.) Although contours are largely seen as unified wholes in the configuration approach, pitch is also meaningful in smaller domains of the utterance. For example, the preceding words in the response in (1) also have a role in the configurations approach, as in (2). The first stressed syllable preceding the nucleus is the start of the Head, unstressed syllables before the Head are

called the Prehead, and the syllables following the Nucleus are called the Tail. The intricacies of the full system of description are beyond the scope of this entry, but all were thought to be meaningful intonational choices.

- (2) He's my very `BEST friend.
prehead | head | nucleus | tail

Intonational Meaning

Intonation contributes to linguistic meaning in a variety of domains, such as marking juncture between spoken phrases, highlighting, or backgrounding particular words or syllables, marking the ends of intonational phrases with movement, and using extremes of pitch range to carry discourse or contrastive meaning. Other types of meaning (e.g., emotional) are only partially connected to pitch variation, and native speakers inconsistently identify emotions from speech (Crystal, 1969; McLemore, 1991).

A mistaken belief is that intonation reinforces grammatical meaning. While intonation may sometimes correlate with syntax (for example, declaratives in English tend to have falling tones in most contexts), intonation is not simply a mirror of grammar. Instead, it provides an independent source of pragmatic or sociolinguistic meaning. Some research has shown that half of all polar questions (yes/no) in English can occur with rising intonation and half with falling (Thompson, 1995). Recent research on Dutch shows that phonological, syntactic and pragmatic factors all serve to distinguish rising intonation and question fall-rise intonations in read and freely spoken questions (Lickley, Schepman, & Ladd, 2005). Modern theoretical approaches to meaning do not assume a direct causal link between intonation and grammar, but the temptation to connect the two remains strong in pedagogical approaches.

The kind of meaning that intonation contributes to an utterance remains a subject of dispute. Pike (1945) believed that intonation directly represents a speaker's attitude toward the content of what is being said, reflecting the commonsense saying, "It's not what she said, it's how she said it." Intonation "modifies the lexical meaning of a sentence by adding to it the speaker's attitude toward the content of the sentence" (p. 21) and that "if a man's tone of voice belies his words, we immediately assume that the intonation more faithfully reflects his true linguistic intention" (p. 22). Although intuitively appealing, attitudinal meaning depends both on other features of linguistic and discourse context and intonational choices (Ladd, 1980; Chun, 2002).

An influential approach to intonational meaning (Halliday, 1967), connected intonation to information structure: that is, pitch movement on the prominent syllable in English highlights new information in a tone unit. Likewise, the use of low pitch on informationally important words signals that the words contain given information that can be expected to be shared between interlocutors in the context. The appeal to new and given information is ubiquitous in materials used to teach English intonation to foreign learners. Brazil (1997), for example, connects new and given information in discourse to the type of nuclear tone used, that is whether it is generally falling, rising, or level. This *discourse intonation* approach has been used in applied linguistics by researchers such as Pickering (2001) and Cauldwell (*n.d.*).

An influential approach to meaning is Pierrehumbert and Hirschberg (1990). Based on Pierrehumbert (1980), it provides a compositional account of intonational meaning. Each domain of intonation (pitch accent, phrasal tones, and boundary tones) contributes abstract meanings to the overall utterance. Adding these meanings accounts for a logical full interpretation of an utterance. While this method is comparable to earlier approaches to

intonational meanings, such as Pike's "contrastive pointing" and O'Connor and Arnold's compositional meaning tied to different parts of the sentence-level contours, Pierrehumbert and Hirschberg's account is too abstract to be applied directly to teaching.

There are still many questions regarding both the description of intonation and the kinds of meanings it contributes to utterances in discourse. In addition to a large body of work on English, intonational research is increasingly carried out for many other languages. European languages remain the most widely studied, with Japanese, Korean, and various varieties of Chinese also having been examined. Much remains to be done in exploring the relationship of tone and intonation, in looking at the intonation of more non-European languages, and in developing applied approaches to intonation that make explicit connections to laboratory phonology approaches and theoretical accounts of intonational form and meaning.

Suprasegmentals: Prosody in Conversation

BEATRICE SZCZEPEK REED

While students of language have been interested in the relations between sounds and meaning since the very beginning of linguistic inquiry, interest in the phonology of natural conversation is a more recent phenomenon. This is the case because traditionally, language has been studied primarily as an abstract system of rules and patterns, rather than an everyday human activity. However, during the second half of the 20th century a strand of research developed for which naturally occurring talk was the principal focus. Conversation analysis (CA), which originated in sociology, and discourse analysis (DA) were adopted by a number of linguists. Phoneticians and phonologists working in this field began to investigate the suprasegmental aspects of speech—that is, intonation, pitch range, rhythm, stress, speech rate, loudness, and voice quality—by following the conversation analytic approach of studying language from the perspective of those who use it—that is, the conversationalists themselves. This entry focuses on the research field that was directly influenced by CA, and has since become known as *interactional linguistics*.

Since the early 1980s, interactional linguists, among them Elizabeth Couper-Kuhlen, John Local, Richard Ogden, and Bill Wells, have brought to light previously undiscovered prosodic practices that show speakers' use and interpretation of prosody on a local level of conversation. The main findings in this area concern three major conversational activities: turn taking, sequence organization, and the accomplishment of specific conversational actions.

When it comes to negotiating over who speaks when, and for how long, participants in naturally occurring conversation draw on a combination of linguistic and interactional cues. For example, finished contributions, or "turns," are typically characterized by syntactic, pragmatic, and prosodic completion (Ford & Thompson, 1996). The prosodic aspect of turn completion takes different forms, depending on which language, and which variety of that language, a participant speaks. For example, Local, Kelly, and Wells (1986) show that in Tyneside English, complete turns involve a slowing down in speech rate toward the end of the turn, a sudden increase and decrease in loudness on the last stressed syllable, lengthening of that syllable, centralized quality on the final vowels, and either a step up or a drop in pitch on the last stressed syllable. Similar sets of features were described by Local, Wells, and Sebba (1985) for London Jamaican English, and by Wells and Peppè (1996) for Ulster English. These works show that participants do not orient to individual prosodic cues on their own, but instead employ clusters of prosodic features—an early warning against a simplified correlation between prosodic cues and interactional functions. Later, Szczeppek Reed (2004) demonstrated that almost any intonation pattern that is part of the repertoire of English tones can occur in turn-final position, and that any analysis of prosody and turn taking requires detailed study of the kinds of turns in question. This means that prosodic cues themselves do not carry any inherent turn-related meaning; for example, low falling pitch does not "mean" turn completion. However, in co-occurrence with other cues it can be used and interpreted by participants as completing a turn, while in different contexts it may be used for other conversational actions.

Bearing in mind this contextual nature of prosody, there are prosodic parameters that do seem particularly relevant for turn taking. Among those that have been studied in detail are pitch accents, rhythm, and voice quality. Schegloff (1998) and Fox (2001) show that in their US American English data, high pitch accents, or “pitch peaks,” that occur at the end of participants’ turns foreshadow upcoming opportunities for transition, or “transition relevance places” (TRPs). Wells and MacFarlane’s (1998) investigation of West Midlands English finds that in their data participants also treat final accents as transition relevant; however, in that variety, the final accent is not a “peak,” but a “valley.” These researchers therefore argue “that it is the occurrence of the final major accent itself that projects an upcoming TRP, and not just the phonetic characteristics of the postaccentual syllables” (1998, p. 288). Once again, the importance of close attention to prosodic variation across accents is demonstrated by these findings: While both speakers of US American English and speakers of West Midlands English orient to final pitch accents as turn-taking cues, their precise prosodic realization may vary considerably.

The following extract from the Santa Barbara Corpus of Spoken American English Part 1 (Du Bois, Chafe, Meyer, & Thompson, 2000) shows an example of a participant orienting to a pitch accent as signaling a TRP. Angela has just told her friend Doris that she is looking for a certain type of senior citizens’ service. Immediately prior to the transcribed section, Doris offers to help and provide this service as a friend. In reply to this offer, Angela comes in with her turn at line 1.

- (1) SBC011 This retirement bit
 1 Angela: WELL,
 2 I would like to hAve it on a ↑BUSIness ↓BAsis <<1>
 wi[th somebody.>
 3 Doris: [w- well
 4 ALL RIGHT;
 5 WE’LL put it on a bUSINESS bASIS,

What is interesting in this exchange is the precise moment at which Doris comes in to speak. She starts up in overlap with Angela, and a superficial reading of the transcript could suggest an interruption. However, looking at Angela’s turn design we can see that immediately prior to Doris’s start up Angela has reached a point in her utterance that is (a) syntactically complete, in that *well I would like to have it on a business basis* is a potentially complete sentence; and (b) pragmatically complete, in that it is a meaningful reply to Doris’s previous offer of help. Prosodically, it ends in a pitch peak, followed by a fall down to the bottom of Angela’s voice range. This prosodic pattern is indicated in the transcript by the upward arrow preceding the word *business*, and the downward arrow preceding the word *basis*. The fact that Doris comes in to speak at precisely this moment is evidence that from her point of view, these cues—and possibly other, gestural cues that we as analysts are not aware of—signal to her that Angela has reached a point of possible completion. And indeed, although Angela has not finished speaking, the prosodic design of her remaining words *with somebody* is produced with very low pitch register, and without pitch accents.

Another research finding that points to speakers’ continuous monitoring of each other’s prosody for turn-taking opportunities concerns the interactional role of speech rhythm. In her work on English rhythm, Elizabeth Couper-Kuhlen discovered that speakers of English tend to continue the rhythmic patterns established by a previous participant’s turn in their own next contribution (Couper-Kuhlen, 1993; Auer, Couper-Kuhlen, & Müller, 1999). As English rhythm tends toward stress timing, stressed syllables occur at roughly regular time intervals. Continuing a rhythm across a turn transition means that a next speaker must produce the first stressed syllable of his or her turn precisely at the moment when,

according to the previous speaker's rhythmic pattern, a next beat is expected. Couper-Kuhlen showed not only that this is the norm for English conversations, but also that interactants treat speaker changes that occur early or late according to a prior rhythm as problematic. This practice means that participants are continuously monitoring the timing of each other's talk with great precision. It also shows that in spontaneous interaction, the placement of utterances at precisely defined conversational locations is treated as meaningful, above and beyond the semantic meaning of the words and sentences involved.

Voice quality deserves specific mention here, as it has traditionally been ignored by most linguists as not bearing meaning. However, Richard Ogden has found that, at least in Finnish, voice quality is used as a turn-taking cue. In Ogden (2004) he shows that a change from modal, that is, default voice quality to combinations of creak, breathiness, and whisper accompanies many turn endings in Finnish, and is treated by conversationalists as turn-relevant. This finding suggests that an analysis of prosody in discourse cannot be restricted to what has traditionally been labeled "suprasegmental." As many non-discourse-oriented linguistic approaches take as their scope of analysis the single sentence, and the single speaker, voice quality does not appear as a contrastive feature in those fields. However, a prosodic parameter used for turn taking can only be observed when the data under analysis are conversations, rather than single-speaker sentences. In this case, therefore, the method and scope of analysis must adapt to a rather different object of study.

A second area in which research on prosody in conversation has been fruitful is the organization of talk into sequences. Here, prosody seems to be particularly involved in one aspect. During an emerging interaction speakers repeatedly encounter points at which they have to signal to their co-participants whether they are continuing a current course of action, or whether they are starting something new. It is at these sequential "forks in the road" that prosody is employed—sometimes exclusively—to show which direction a speaker is taking. For example, Local (1992) shows that when participants interrupt the course of their own current turn, the prosodic design of their talk following this interruption shows whether they are continuing the turn they were engaged in before, or whether they are beginning a new turn, thus aborting the previously unfinished utterance. One prosodic parameter that is used for this purpose is pitch register, that is, a participant's overall pitch level. Talk that is designed as continuing a previous turn continues the pitch register of that previous turn: the pitch level at the beginning of the continuation matches precisely that at which the speaker previously left the abandoned turn. In contrast, talk that starts something new begins with higher pitch. Couper-Kuhlen (2004) also describes how participants use a sudden increase in pitch and loudness when they are starting a new conversational sequence; and continue previous pitch and loudness levels when they are continuing what they were previously in the process of doing.

A slightly different practice is described in Szczepek Reed (2009). While the above-mentioned research reports that an increase in pitch and loudness is typically associated with a new conversational activity, this work explored an underlying principle according to which newness is achieved prosodically by doing something different to prior talk as such; however, not necessarily by using a particular prosodic design, such as higher pitch or loudness. Szczepek Reed (2009) shows that by either repeating or not repeating a previous speaker's prosodic patterns, participants indicate whether they are continuing a sequence or starting a new one. This even holds for cases such as greeting sequences, in which participants may use the same lexical token—such as *hello* or *hi*—to respond. Next speakers may either match the prosody of the prior greeting, thus offering a continuation of the greeting sequence, or not match the previous prosodic pattern, and thus start a new greeting sequence, to which the previous speaker then replies with a return greeting.

The third area of discourse in which prosody plays a major role is the accomplishment of specific conversational actions. A large amount of research has been carried out on the

prosodic configurations of specific types of turns and actions. From the perspective on prosody in discourse, the most interesting cases are actions that are distinguished exclusively by their prosodic design. In her research on quoting and reported speech in interaction, Couper-Kuhlen (1996) found that conversationalists use two different prosodic patterns for the distinct activities of quoting and mimicking an immediately previous speaker. Both cases involve a next speaker's matching a previous speaker's pitch register. However, participants distinguish clearly between two ways in which this can be achieved. In instances of "quoting," next speakers repeat a previous speaker's register on a relative scale, that is, they use the same register according to their own voice range. For example, in the case of a female first speaker whose utterance is delivered with high pitch register, a man quoting her adopts a pitch register that is high in his own range. On the other hand, instances of "mimicking" involve pitch register matching on an absolute scale. In this case, the male speaker repeats precisely the pitch register of the previously speaking female participant, resulting in a pitch register that is situated extremely high in his voice range. While quoting is interactionally neutral, mimicry is used as a strategy for criticism or derision. In both cases, the second speaker's turn contains verbal repetition of the previous participant's utterance. It is only the prosodic design that gives away the conversational activity of that repetition as being an instance of quoting on the one hand, or mimicry on the other. Couper-Kuhlen's work on mimicry, and on rhythmic integration, and Szczepek Reed's work on matching prosodic patterns in greeting sequences (mentioned above) shows that continuing a previous speaker's prosody is an integral part of conversation. However, there seems to be a degree at which such *prosodic orientation* (Szczepek Reed, 2006) becomes "too much," and can turn into sarcasm and a display of interactional power relations.

A very different conversational action has been described by Auer and Rönfeldt (2004) in their work on aphasic speech. Their analysis of the speech of one particular patient with aphasia reveals that a prosodic practice described in medical-oriented literature as "prolixity," and treated there as a symptom of the cortical brain injury, is in fact a conversational strategy to overcome word retrieval problems. The practice in question involves producing an utterance from which the main element is missing, yet which is decreasing in loudness—typically a prosodic sign for turn completion. Immediately following this aborted utterance the speaker starts up again at a higher loudness level. This practice makes it difficult for co-participants to join in, as the speaker's prosodic cues continuously contradict the semantic/pragmatic content of his or her utterances. However, Auer and Rönfeldt show that the practice of designing his incomplete utterances as complete, and starting up immediately afterwards with a next turn, allows the aphasic speaker to conceal word retrieval problems in a face-saving manner. The prosodic pattern and the resulting conversational difficulties are revealed to be interactional strategies, rather than direct consequences of brain injury.

Recent decades of research on prosody in conversation have shown that prosody must be taken seriously as a relevant interactional parameter. However, the work in this field has also demonstrated that prosody must be studied in the context of the many other interactional resources participants have at their disposal. Therefore, it is in the combination of those different spheres of influence that the complexities and challenges for an understanding of prosody lie.

Suprasegmentals: Rhythm

YUKARI HIRATA

Overview

Research in rhythm has progressed over the past 70 years involving multiple disciplines such as phonetics, phonology, psycholinguistics, first and second language acquisition, cognitive science, neuroscience, and developmental psychology. One major question has been whether languages of the world can be categorized into a certain number of rhythm classes based on a given definition in phonological, acoustic, articulatory, or perceptual terms. This question of rhythm typology also includes the issue of whether there are distinct rhythm classes with measurable indices in empirical data, or whether language rhythms differ in a gradient, instead of categorical, fashion; e.g., Spanish not belonging to the same rhythm class as French, but being closer to French than to English. The presence of rhythm in language is uncontroversial, but it has been a challenge (or a fascinating problem), to describe, define, and prove rhythms of world languages in terms that can be agreed upon.

Researchers have also explored questions such as: How do infants acquire a native language rhythm, and how does their earlier knowledge of rhythm help them to segment speech streams and learn individual words and sentence structures? Is it possible for adults to acquire second language rhythms perfectly? Is the perception of rhythm language-specific or species-specific, or does it involve more general auditory mechanisms shared by humans and other primates? What is the role of rhythm in perceiving spoken words? How does the perception of one's native language relate to the perception of nonspeech rhythm as in music or simple sequences of beeps? How is the perception of speech rhythm reflected in brain function?

Rhythm Typology of the World's Languages

Earlier studies between the 1940s and 1960s identified three major rhythm classes: *stress-timed*, *syllable-timed*, and *mora-timed*. In stress-timed languages, such as English, stressed syllables are said to recur at equal time intervals, whereas in syllable-timed languages, such as French, all syllables recur at equal intervals. This rhythmic recurrence, or *isochrony*, was proposed on the basis of how languages are produced, and thus was examined by acoustic analysis of produced speech. However, studies failed to find a definitive answer to explain the presence of isochrony in measured duration of intervals, e.g., between stressed syllables in English, although this tendency was observed (Lehiste, 1977, 1980). Dauer (1983) found that interstress intervals of stress-timed languages such as English and Thai are no more isochronous than those of syllable-timed languages such as Spanish, and argued that the traditional rhythm classification is not supported by phonetic and acoustic investigations. One challenge of acoustic analysis of naturally produced speech is that speech signals are bound to be so variable that it is difficult to make a conclusive judgment about whether measured intervals of, for example, 85 milliseconds and 100 milliseconds are similar enough to be considered as evidence for isochrony.

A turning point in rhythm studies was the idea that this rhythm classification has mostly to do with differences in phonological structures, and not with isochrony in acoustic signals (Dauer, 1983). One example is a phonological rule governing whether unstressed vowels are reduced or not in a given language, e.g., the English word *to* /tu:/ is reduced to /tə/ when it is unstressed in a sentence. This vowel reduction affects the overall rhythm, since the reduced vowel is consistently shorter in duration. Dauer (1983) also pointed out that rhythm differences appear according to how complex syllable structures are in each language. For example, in French 74% of syllables are open (e.g., CV and V) and only 26% are closed (e.g., CVC and CVCC), whereas in English 44% of syllables are open and as many as 56% are closed. She also argued that the notion of the stress-timed and the syllable-timed rhythms does not refer to two distinct categories but rather to gradient characteristics in a continuum: a particular language could be more or less stress-timed or syllable-timed than others.

The third rhythm class that has been identified is *mora-timed*, in which isochrony is expected to exist in the unit of the mora. Moras are similar to syllables but length-sensitive, e.g., a syllable with a long vowel counts as two moras, and each mora takes about the same amount of time to say. For example, in Japanese, /ko:ko:/ with two long vowels, meaning 'high school,' and /kudamono/, 'fruits,' take about the same amount of time to say—each word containing four moras. Mora isochrony is another independent topic investigated over 50 years. Many studies support the existence of mora isochrony in various acoustic/durational measures (e.g., Port, Dalby, & O'Dell, 1987), but other studies do not (e.g., Warner & Arai, 2001).

Evidence of Rhythmicity in Speech Signals

Another turning point of rhythm studies was in the 1990s to 2000s, when researchers revisited the question of duration in search of acoustic evidence for the stress-timed, syllable-timed, and mora-timed classes. Unlike earlier work by Lehiste (1977, 1980), studies by Ramus, Nespor, and Mehler (1999) and Grabe and Low (2002) did not search for isochrony but adopted different approaches. Ramus, Nespor, and Mehler (1999), for example, calculated more global measures, such as the proportion of summed vocalic intervals (such as vowels) over the entire sentence duration (%V), and the standard deviation of consonantal intervals over the sentence (ΔC). Ramus et al. (1999) found that these two measures were successful in classifying the eight languages they examined: English, Polish, and Dutch as stress-timed languages; French, Spanish, Catalan, and Italian as syllable-timed languages; and Japanese as a mora-timed language. According to these acoustic indices, rhythm is defined in terms of how much the overall vocalic portions occupy as a proportion of the whole utterance (%V), and how variable the consonants are (ΔC , partially reflecting on syllable complexity such as CV, CCV, CCCV, VC, CVC, CVCC, etc.) in the entire produced utterance.

Grabe and Low (2002) also took an approach that departed from the traditional search for isochrony. They examined *pairwise variability indices*, which express the level of durational variability in successive pairs of vocalic portions (vocalic PVI) or successive pairs of intervocalic or consonantal portions (intervocalic PVI). They were successful in classifying British English, German, and Dutch as stress-timed languages and French and Spanish as syllable-timed languages, although they could not classify Japanese as a separate class of mora-timed language. Their data, however, looked more complex when 18 languages were examined altogether. On the question of the categorical or gradient nature of rhythm classification, their data suggested it to be "weak(ly) categorical" (p. 10).

Rhythm as a Perceptual Entity

Two criticisms have been raised about the approach that searches for evidence of rhythmicity in duration of speech signals. The first is that rhythm cannot be captured accurately when we attempt to characterize it exclusively with *produced* acoustics of speech, and that we need to take *perception* into account (Kohler, 2009). Lehiste (1977) showed that English listeners tend to *hear* interstress intervals as being more isochronous than they actually are in production. The earlier notion of rhythm as described in Woodrow (1951) was “the perception of a series of stimuli as a series of groups” (p. 1232). Only a few studies (Ramus, Dupoux, & Mehler, 2003) examined native adults’ perception of rhythm as evidence for the existence of rhythm classes.

The second criticism arises if we consider that the way we *perceive* speech rhythm is an essential part of characterizing or defining it. Researchers (e.g., Arvaniti, 2009) have pointed out that perceptual rhythmicity is described in terms not only of duration, but also of fundamental frequencies (which are associated with our perception of pitch height) and intensity (which is related to our perception of signal strength). They point out that studies which only focus on *timing*, looking exclusively at the durational aspect of speech, would miss an important point about how we perceive rhythm. They argue that rhythm studies should focus on perceptual utilization of duration, fundamental frequencies, and intensity in grouping and patterning of prominence (which differ greatly from one language to another), and that the search for a single acoustic index of duration is misguided. Even the idea that stress-timed versus syllable-timed rhythm classes are valid categories has been questioned (Arvaniti, 2009).

Rhythm as Entrainment

Another line of approach has been to view rhythm as a psychological entity that has a tendency to entrain in speech syllable chains (Port, Cummins, & Gasser, 1995; Tajima, Zawaydeh, Kitahara, & Port, 2000). Their approach utilizes a *speech cycling* paradigm, in which speakers are asked to repeat a phrase over and over with the guidance of a metronome. It examines whether salient parts of speech, such as stressed syllables, fall at rhythmic intervals. Port et al. (1995) asked speakers to repeat an English phrase, *Take a pack of cards*, and measured the point in time where the final stressed syllable, *cards*, fell in the interval between the first stressed syllable, *take*, in one repetition and that in the next repetition (i.e., the total phrase interval). The hypothesis was that if speakers do not have internal rhythmicity in their speech, the points of time when the last stressed syllable (i.e., *cards*) occurs would be random, but if they have an internal oscillator for entrainment, the occurrence of *cards* would fall at predicted phases such as 1/3, 1/2, and 2/3 of the total phrase interval. The results supported this hypothesis: Of many trials of the produced phrase, the most frequent occurrence of the final stressed syllable was at the point near 1/2 of the total phrase interval, and the second frequent occurrence was at the point near 1/3, and the third near 2/3. This kind of regularity is not normally observed in spontaneous speech of various lengths due to constraints of articulatory gestures needed to produce variable consonants and vowels. However, this approach attempts to capture the underlying production mechanism that is responsible for speech rhythm.

Of interest to applied linguists are experiments that compared different languages with this speech cycling paradigm. Tajima et al. (2000) examined production of several sentences differing in the locations of stressed and unstressed syllables in English and Arabic, and those differing in the locations of pitch accent in Japanese. Their results for English and Arabic were similar to those of Port et al. (1995) mentioned earlier. The final *stressed* syllable

in both types of sentences such as *BUY DOUG a BEER* and *GIVing the GIRL a DOUGHnut* (stressed syllables in upper case) fell at the point near 1/2 of the total phrase interval. This indicates that it is not *any* final syllable that falls at the 1/2 point, but it is the *stressed* syllable that makes up the rhythmicity. In contrast, for Japanese, it was consistently the final syllable (or mora), regardless of the location of pitch accent, that fell at the 1/2 point in sentences such as *dokudami da* ('It is chameleon plant' with no pitch accent) and *goma dare daKE da* ('It is only sesame dressing' with the pitch accent in the second-to-last syllable, marked in upper case). Experiments with the speech cycling paradigm, thus, can demonstrate cross-linguistic differences in the manifestation of rhythm.

Rhythm and Language Acquisition

Abundant research in infant speech acquisition includes the work of Nazzi, Bertoncini, and Mehler (1998), who found that five-month-olds were able to discriminate rhythms of languages across rhythm classes, e.g., English (stress-timed) versus Japanese (mora-timed), but did not discriminate rhythms of languages within the same rhythm class, e.g., Italian versus Spanish (both syllable-timed). Given the traditional notion of stress-, syllable-, and mora-timed rhythm classifications, we might ask questions such as how native adult speakers of a syllable-timed language learn a stress-timed language, or how a speaker of one rhythm class might be negatively affected when learning a language of the other rhythm class. Does the rhythm of one's native language transfer positively when learning a second language of the same rhythm class? Is it premature to ask these questions when we do not have solid agreement about the rhythm classes as discussed in earlier sections?

White and Mattys (2007) point out that caution is needed when interpreting data of non-native speakers with regard to rhythmic indices, as touched on above. For example, they point out that the rhythm index ΔC of Ramus et al. (1999), i.e., the standard deviation of consonantal intervals, shows an inverse correlation with speech rates. Thus, even if native speakers of Spanish learning English showed a high value in ΔC , which is an expected characteristic of English, this result might not mean that they have mastered native-level English because the high ΔC value might simply mean that they spoke English slowly because they were second language learners. White and Mattys (2007), however, solved this problem by normalizing the speech rate, and showed that rhythmic indices can be useful in characterizing non-native speakers' production of rhythm. Using the rate-normalized standard deviation of vocalic interval duration, they showed that native English speakers' English had the highest value, native Spanish speakers' Spanish had the lowest value, and English speakers' Spanish and Spanish speakers' English had values somewhere in between.

Studies in the acquisition of speech rhythms are not limited to those that focus on rhythm classes. Trofimovich and Baker (2007) examined the durational ratio of unstressed to stressed syllables in spoken English, and compared the ratios between native English speakers and native Korean speakers learning English. Lee, Guion, and Harada (2006) examined both the duration and intensity ratios of unstressed to stressed syllables in characterizing English produced by Japanese-English and Korean-English bilinguals who started learning English at the ages of 1 versus 15–16. Tajima (2005) examined native Japanese speakers' (in)ability to count the number of English syllables. As mentioned before, Japanese is considered to be a mora-timed language, and the inability of Japanese speakers to count English syllables was affected by a number of factors, such as syllable structure complexity (Tajima, 2005). Hirata (2004) examined native English speakers' (in)ability to count moras in Japanese words of one to six moras in length, e.g., /ko/ 'children' with a short vowel (one mora) and /ko:/ 'this way' with a long vowel (two moras). Results

showed that native English speakers were unable to count moras accurately and biased to count syllables (one syllable in both of the above examples) due to their inability to perceive length contrasts, but that their perception improved through auditory training. Finally, a series of studies examined how speakers of various languages segment a series of consonants and vowels, and differential results revealed distinctions in their rhythm classes (e.g., Murty, Otake, & Cutler, 2007). Crosslinguistic research in rhythm is rich and multifaceted, and in the future will continue to provide insights into issues regarding both acquisition and rhythm typology.

Suprasegmentals: Stress

REBECCA HINCKS

Stress is a feature of pronunciation in which a syllable is given more emphasis than surrounding syllables. It is intrinsically contrastive: A single syllable cannot be stressed in isolation, but only in relation to other syllables. Stress is a critical aspect of the pronunciation of multisyllable words. The term “stress” has also been used by some scholars in connection with the word in an utterance that has been emphasized by the speaker—for example, *I only wanted ONE potato* (not two or three). This emphasis has been termed, for example, “sentence stress,” “contrastive stress,” or “nuclear stress.” However, these terms are misleading, because the kind of stress produced here functions at the discourse level, using intonation to produce meaning. This contrasts with the use of the term to describe features of a word’s pronunciation, which is more or less fixed, instead of variable depending on speaker intent. Better terms for “stress” at the discourse level use the words *accent*, *prominence*, or *focus*. This entry will deal primarily with word-level stress, which is also known as lexical stress.

Stress can be difficult for some people to consciously perceive, particularly for non-native speakers of a language, but also even for some native speakers. It can be helpful to begin by considering how stress patterns are used to create rhythm in poetry and song, for example, the opening lines of the well-known “A Visit from St. Nicholas,” attributed to Clement Moore (Anonymous, 1823):

’Twas the NIGHT before CHRISTmas, when ALL through the HOUSE
Not a CREaTure was STIRRing, not EVen a MOUSE
The STOCKings were HUNG by the CHIMney with CARE
In HOPES that Saint NICHolas SOON would be THERE

Throughout the poem, two unstressed syllables are followed by a stressed syllable (a type of metrical foot known as an anapest), though the beginning of each line can be either one or two unstressed syllables. The one-syllable words that are stressed are generally content words, and the unstressed words are generally function words such as prepositions, articles, and auxiliary verbs. The two-syllable words (*Christmas*, *creature*, *stirring*, *even*, *stockings*, and *chimney*) are all stressed on the first syllable, as is the one three-syllable word (*Nicholas*). These are the standard pronunciations of these words—the word *CREaTure*, for example, would be mispronounced if one were to say *creaTURE*—and their stress patterns have been used to create the rhythm of the poem.

Germanic languages like English have a strong preference for the alternation of stressed (or strong) syllables with unstressed (or weak) ones. Strong syllables always contain full vowels, while weak syllables have reduced vowels, most often schwa. In traditional poetry, words are deliberately arranged into feet of two or three syllables following a specific pattern. In connected speech, syllables can also be grouped into feet analogous with the bars of musical notation. Germanic languages also have a strong tendency toward isochronicity, that is, the production of stressed syllables at roughly equal intervals in continuous speech, with unstressed syllables—whether there are one, two, three, or even more of them—filling the gaps between them. This phenomenon is also known as stress

timing. Other languages, among them French and Spanish, tend toward what is known as syllable timing, in which all syllables are produced with largely equal weight. Many scholars (e.g., Cruttenden, 1986; Jenkins, 2000) have pointed out that these distinctions should not be taken as binary contrasts, but rather scalar differences. Nevertheless, mastering the pronunciation of a second language (L2) where stress peaks are produced differently than in one's native language can be a challenge for many learners.

Research has shown that we may rely on stressed syllables for word segmentation in streams of continuous speech (Cutler & Norris, 1988). In many languages, stress appears in a relatively fixed position within the word. With morphological exceptions, the first syllable of the word is stressed in Czech and Finnish, while the penultimate syllable receives stress in Spanish and Welsh, and the final syllable in French and Turkish. English, however, allows for stress to be placed in any syllable of a multisyllable word. The language contains a number of pairs of words where the grammatical class of the word is distinguished by stress placement. Many of these are noun–verb pairs, such as *REcord/reCORD* and *PREsent/preSENT*, where the noun is stressed on the first syllable and the verb on the second syllable. Adjectives can also be contrasted with verbs or nouns, as in *PERfect/perFECT* and *conTENT/CONTENT*. Lexical meaning distinguished by stress is also a feature of other languages, for example, German (*UMfahren/umFAHren*, 'to drive over something' vs. 'to drive around something') Dutch (*beDElen/BEdelen*, 'to give everyone one's part' vs. 'to beg') and Italian (*PRINcipi/prinCipi*, 'princes' vs. 'principles'). While these minimal pairs can be useful to illustrate what stress is, it should be noted that stress distinctions do not carry a high functional load in any language (Cruttenden, 1986).

Words of more than two syllables can emphasize more than one syllable by using secondary stress as well as primary stress. The word *TEleVIsion* in English, for example, has primary stress on the first syllable, and secondary stress on the third syllable. In International Phonetic Alphabet (IPA) notation, primary stress is shown by a small vertical line above the beginning of the stressed syllable, and secondary stress by one below the beginning of the syllable, so that the dictionary entry reads /'tɛləˌvɪʒ(ə)n/. Phonetic notation also reveals the extent to which the unstressed syllables are reduced, so that both the second and fourth syllables of *television* are pronounced as schwas.

There are a few rules that can be learned regarding which syllable in a word should be stressed in English. One governs compound nouns, which are stressed on the first syllable of the compound to distinguish the referent from a non-compound. For example, when we say *HOTdog*, the referent is a food item rather than a *hot DOG*, meaning a suffering pet. There is only one *WHITE House* in the United States, while there are many *white HOUSES*. The non-compounded combinations, where nouns and adjectives are freely combined, are known as phrases, and receive stress on the final element of the combination, such as *a pretty PICTure* or *an old BUILding*. A number of words in English shift stress placement with the addition of morphemes, suffixes, or prefixes. For example, the word *PHOtograph* becomes *phoTOgraphy*, *photoGRAPHic*, or *photoGRAPHical*. In this class of words, many of which originate from Greek, there is a tendency for the third syllable from the end to be stressed, in what is known as antepenultimate stress.

Beyond the rules for compounds, phrases, and morphological shifting, the situation for predicting stress placement in English becomes more complicated. Theoretical approaches were undertaken by the generativist school with the goal of deriving extensive stress rules (e.g., Liberman & Prince, 1977), and this work found pedagogical application in the work of Dickerson (e.g., Dickerson & Finney, 1978). More recent work takes a descriptive rather than a theoretical approach, by looking at stress patterns in specific corpora. In a study whose purpose was to find techniques to improve the accuracy of automatic speech recognition, Cutler and Carter (1987) found that 90% of content words in conversational English (the London–Lund Corpus) either were monosyllabic or began with a stressed

syllable. Of the polysyllabic words in the corpus, 70% had primary stress on the first syllable, a proportion that could be useful and reassuring to know for L2 speakers uncertain about where to stress words. However, stress patterns become slightly more complicated when less frequent vocabulary is examined. The Academic Word List (Coxhead, 2000) contains the 570 word families above the 2,000 most frequent in academic writing. These words are likely to be encountered by language learners primarily in writing, and it is important that uncertainty about how they are stressed should not present a barrier to using them in speech. Murphy and Kandil (2004) found that 14 different stress patterns characterize 90% of the polysyllabic words in the word list. While 14 is a manageable number of patterns to learn for students who have the benefit of focused instruction in pronunciation within the bounds of an English for academic purposes (EAP) program, it is also evidence of the diversity of stress patterns in this type of English vocabulary. Learners (and sometimes their instructors) can also be confounded by the fact that there exists as well a fair degree of variation in stress placement between varieties of English (Gimson, 1980), and by the fact that polysyllabic, etymologically foreign words such as *parameter* can be cognates between languages, differing often in stress placement, and thereby at risk of being treated as a false friend in the L2.

How Stress Is Produced Acoustically

The extra emphasis given to a stressed syllable is a product of the three basic elements of prosody: pitch, duration, and intensity. A stressed syllable is higher in pitch, longer, and louder than its surrounding syllables. Researchers are not necessarily in agreement as to whether any one of these features plays a dominant role in our perception of stress. One theory is that the strongest perceptual cue is higher fundamental frequency (what is perceived as pitch), with duration and intensity coming in second and third places respectively (Lehiste, 1970), but other writers point to duration (e.g., Liberman & Prince, 1977) or to intensity (e.g., Crystal, 2008) as being most salient. It may also be the case that languages, or even individual speakers, vary in the extent to which they employ one feature or another in the production of stress (Jenkins, 2000).

Figure 1 shows an acoustic analysis of a male radio journalist's production of the phrase *it was technology that took us to the moon*. This utterance contains one four-syllable word where lexical stress placement is an issue, and eight monosyllabic words which can also receive emphasis at the discourse level, using the same acoustic means as those that create lexical stress. The analysis window here shows information about pitch and duration, but not loudness. The bottom half of the figure represents pitch movement, with rising pitch on the second syllable of the word *technology*, as well as the words *took* and *moon*. The waveform at the top of the figure reveals that the second syllable (circled) in *technology* is somewhat longer than others, except for the final syllable of the utterance. The longer duration and rising pitch of the second syllable of *technology* show that it is stressed as it should be in standard English, and indicate its function as a "docking site" (Wennerstrom, 2001, p. 47) for pitch accent in the utterance. Two monosyllabic content words are also accented within the utterance, *took* and *moon*, and the lines from *no* to *took* and from *took* to *moon*, which are copies of each other, illustrate that the pitch peaks that appear at the ends of these syllables are equally distant from each other in time (isochronicity).

Teaching Stress

Knowing where to put stress in a multisyllable word is part of knowing the word's pronunciation. Misplaced stress on words spoken in isolation can impede intelligibility for

Figure 1 An acoustic analysis of a professional speaker's production of the utterance *it was technology that took us to the moon*, showing waveform, spectrogram, and fundamental frequency (pitch)

Note. Encircled parts of the waveform correspond to lengthened syllables, and the lines from *no* to *took* and from *took* to *moon* indicate equal length between pitch peaks (isochronicity).

both native and non-native listeners (Field, 2005). However, the extent to which misplaced lexical stress creates problems in actual lingua franca communication is unclear (Jenkins, 2000).

Learners require both the ability to produce stressed and unstressed syllables with automaticity, and the knowledge of the correct stress pattern. Successful teaching techniques for production and perception of stress include physical responses (Gilbert, 2005) such as tapping, clapping, or stretching elastic bands on the stressed syllable—techniques that heighten awareness of stress but focus more on its temporal aspects (its longer duration) rather than on the pitch movement that is also an important acoustic correlate. Speaking words through kazoo's or humming them gives concrete feedback as to whether pitch has been raised on stressed syllables, while chanting rhythmically (Graham, 1978) allows natural language to be used and should encourage pitch movement as well as rhythmic variation. Practicing pronunciation with the help of computer-based speech analysis can visually demonstrate to students when they have been successful in using pitch movement to stress words. Teaching effort must be put into teaching not only how to stress syllables, but also how to reduce unstressed syllables by altering vowel quality toward schwa.

Learners also need to know what pattern to apply to new vocabulary items. They should at the very least be taught the most productive stress pattern rules, and how to identify stress notation in dictionary entries. Murphy (2004) describes a teaching technique that establishes conventions for discussing stress patterns with students, whereby words are classified according to their number of syllables and the syllables that have primary and secondary stress. Grouping words by stress patterns has psycholinguistic validity, insofar as there is strong evidence that a word's stress pattern plays a role in how it is stored in our mental lexicon (Aitchison, 2003).

Suprasegmentals: Tone

RATREE WAYLAND

Voice pitch is used to change word meaning in the majority of the world's languages. Such languages are referred to as tone languages. In these languages, words change their meanings depending on the voice pitch, or tone, used to produce them. These lexical tones are characterized by their pitch height, or register (e.g., high, mid, and low), and their pitch contours (e.g., level, falling or rising). Mandarin Chinese, for example, has four contrastive tones: tone 1 (high level), tone 2 (mid-high rising), tone 3 (low falling-rising) and tone 4 (high falling). Thus, in Mandarin, the consonant + vowel string *ma* spoken with tone 1 means 'mother', with tone 2 means 'hemp', with tone 3 means 'horse', and with tone 4 means 'a scold or reproach'. Despite their prevalence among the world's languages, tone languages remain understudied, and much remains to be learned about their linguistic structures and representations as well as their processing and acquisition.

Tone Languages of the World

Tone languages are found mainly in Africa, East and South-East Asia and the Pacific, and the Americas.

African tone languages are characterized by having fewer contrastive tones than those spoken in East and South-East Asia. Tonal inventories of many African tone languages show only a two-level tone contrast, high versus low; contour tones, which are widespread in Asian tone languages, are rare.

A smaller tonal inventory in African tone languages is compensated for by its richer and more complex tonal behaviors due to its interaction with the languages' rich word-formation systems (morphology). Unlike Asian and Pacific tone languages, where tones are lexically associated with a specific syllable or word, tone association in African languages is usually phonologically controlled: Phonological rules tend to place tones at the edges of words, on prominent syllables, at phrasal boundaries, and so forth (Yip, 2002). Such phonological phenomena as tone spreading, deletion, and alternation are also common among African tone languages, resulting in a rich and complex tonal phonology.

Asian tone languages are characterized by their larger tonal inventories, simpler morphology, and less complex tonal phonology. Tone languages spoken in the Americas, on the other hand, exhibit a larger tonal inventory than those of African tone languages, but their morphology and tonal phonology are less complex.

Similar to those of African tone languages, syllable structures of Asian and Pacific tone languages are rather simple, consisting frequently of only an initial consonant and a vowel with or without a final consonant. Tonal contrasts thus serve to increase what would otherwise be the small number of possible syllables in these languages.

Lexical Tone Notations

Phonetic transcription practices of lexical tones vary among linguists working with tone languages from different regions.

2 SUPRASEGMENTALS: TONE

African

Africanists mainly employ acute (´), grave (`), and level (ˉ) accent marks to represent the high, the low, and the mid tones respectively; for example,

High	bá	
Low	bà	or unmarked
Mid	bā	or unmarked

Low and mid tones are sometimes left unmarked, particularly when they are analyzed as the default tone contrasting with the phonological high tone.

Asian

Linguists working on East Asian tone languages commonly use the “Chao tone letters” system to represent tones. In this system, a speaker’s pitch range is divided into five equal levels, with 1 representing the lowest pitch range and 5 the highest. A sequence of numbers represents the contour of the tone: Level tones are represented with a single digit or two of the same digits, and contour tones are represented with two or three digits. Zero digits means the syllable does not have a phonological tone of its own. These digits are written next to the syllable and may be accompanied by a diagram indicating the tonal shape. For example, level and contour tones of a hypothetical Asian tone language may be represented as follows:

Level tones	High	na55 ˊ
	Mid	na33 ˋ
	Low	na11 ˉ
Contour tones	Falling	na51 ˋˊ
	Rising	na35 ˊˋ
	Low falling-rising	na215 ˋˊˊ

Among South-East Asianists, the Chao number system is also accompanied by a grave (`) accent mark, an acute (´) accent mark, or their combination (ˆ, ˇ) placed above the vowel of each syllable to indicate a low, a high, a falling, and a rising tonal contour respectively. A mid tone is usually left unmarked. The five phonemic tones in Thai, for example, are represented as follows:

Mid (falling)	na:32	‘rice field’
Low (falling)	nà:21	‘a nickname’
(High) falling	nâ:51	‘face’
High (rising)	ná:45	‘aunt’
(Low falling-)rising	nǎ:213	‘thick’

The Americas

Americanists also use digits to transcribe tones. However, the digits are reversed from the Asian tradition, so that 5 represents the lowest pitch range while 1 represents the highest. Level tones are represented with a single digit, and a hyphen is often inserted between the two digits representing a contour tone; for example:

Level	High	ka1
	Low	ka5
Contour	Low rising	ka5-3
	High falling	ka1-3

Tone Processing

Besides F_0 (fundamental frequency), lexical tone consists also of other acoustic features. These include duration, amplitude, and phonation type (e.g., breathy, creaky). In Mandarin Chinese, tone 3 has the longest duration and tone 4 the shortest. The amplitude of tone 3 is the lowest while that of tone 4 is the highest. Tone 3 is also often produced with a creaky voice. Thus, in addition to pitch, length, loudness, and phonation type also facilitate tonal discrimination.

Besides determining acoustic dimensions employed in tone perception, researchers are also interested in brain lateralization during auditory processing of lexical tones. It has been suggested that processing of linguistically relevant auditory events is predominantly lateralized to the left hemisphere. Under this functional account, pitch should be processed predominantly in the left hemisphere among native tone-language listeners, given that pitch carries a linguistic function in these languages. Evidence taken to support this hypothesis was provided by studies using dichotic listening tasks in which tones were presented simultaneously to both ears for identification. A right-ear advantage (REA) was reported for native Thai and Mandarin Chinese speakers, suggesting left-hemisphere dominance in lexical tone processing among native tone listeners (Van Lancker & Fromkin, 1973; Wang, Jongman, & Sereno, 2001). Further evidence in support of left-hemisphere dominance in lexical tone processing comes from studies on aphasic patients with left-hemisphere damage (Gandour & Dardarananda, 1983). Absence of REA was, however, also found in some dichotic listening studies (Baudoin-Chial, 1986). In addition, an REA was not found for every native tone listener. Furthermore, a possible confounding influence of brain processing of real-word stimuli (in which the pitch is embedded) that were used in some previous studies has been suggested (Wong, 2002). Thus, our knowledge of how lexical tones are processed by the brain remains incomplete, but will likely be improved with a more refined methodology.

Lexical Tone Acquisition

In comparison to the acquisition of vowels and consonants, research on how both children and adults perceive and produce lexical tones remains scarce. A study by Harrison (2000) showed that Yoruba-learning infants were more successful at detecting pitch difference in isolated syllables than were English-learning infants. Mattock and Burnham (2006) reported the ability to discriminate Thai lexical tone contrasts and their analogous nonspeech (violin-sound) tone contrasts among Chinese-learning infants at both 6 and 9 months of age. In contrast, 9-month-old English-learning infants, but not 6-month-olds, showed a decline in lexical tone discrimination, while their discrimination of the violin tones remained intact. Mattock, Molnar, Polka, and Burnham (2008) also found that English and French infants alike failed to discriminate a Thai tone contrast at 9 months of age. These results suggest that the linguistic function of pitch in the ambient language affects its perception in infancy. Specifically, perceptual sensitivity to a lexical tone contrast seems to decrease among infants whose ambient language is nontonal, but remains intact among tone-language-learning infants. Interestingly, this perceptual reorganization occurs between 6 and 9 months of age, the same age range reported for vowel and consonant.

Research on lexical tone production in childhood is also scarce. The focus of some studies, mainly on Asian tone languages, has been to determine the order of tonal acquisition. Li and Thompson (1977) found that Mandarin tone 1 was produced the earliest, followed by tone 4. Tone 2 and tone 3 were easily confused and were the last to be acquired. Cantonese high level (55) and low level (11) tones were produced first by Cantonese children, followed by the mid level (33) and the rising (25) tones. The low rising (13) and the low level (22) tones were the last to be acquired (Tse, 1978). Tuaycharoen (1977) found the Thai mid (falling)

and low (falling) tones appeared first at around 1 year of age, followed by the (low-falling) rising tone. The (high) rising and (high) falling tones did not appear until four months later. These findings are interesting as it is well documented that the mid (falling) and low (falling) tones are the most challenging for native Thai-speaking adults to discriminate. The finding that Thai (low-falling) rising tone was produced earlier than the high (rising) and (high) falling tones is almost the opposite of that found for Mandarin children, suggesting that tonal acquisition order is language-specific and may depend on tonal inventory size, frequency of occurrence, and relative acoustic and auditory saliency of tones in the system.

In Africa, the research focus is on the age at which the tonal contrast is acquired, given that most African tone languages only have a two-tone contrast. Demuth (1995) reported that the contrast between the high tone and the default low tone on root verbs in Sesotho was acquired by the age of 3. This seemingly older age of tonal mastery among Sesotho children may be due to the complex relationship between morphology and tonal phonology discussed earlier.

Regarding relative age of tone and segmental acquisition, studies have suggested that children have full control of lexical tone production by the age of 2, prior to their mastery of segmental production. A child in Li and Thompson's (1977) study, for example, was able to produce a Mandarin utterance with perfect tones, but with less than adult-like consonants.

Studies on lexical tone acquisition among adult second language (L2) learners are also sparse. In general, perceiving a lexical tone contrast is challenging for non-native listeners. Perceptual error rates, however, vary across tones and contexts. This perceptual difficulty may be due to the way non-native tone listeners process lexical tones. Unlike native listeners, non-native tone listeners place more emphasis on the average F_0 and extreme end points and less on the F_0 contour information when identifying tones. Tone perception is also less "categorical" among non-native listeners. Furthermore, non-native listeners do not perceive pitch and segmental information in an integrated manner, and thus an irrelevant change in one affects perception of the other.

Tone production is also challenging for non-native tone speakers. Both tonal height and tonal contour errors have been documented. American-English-speaking students of Mandarin, for example, tend to produce Mandarin tone 1 (high level) with a falling contour and a pitch register that is too low in their tonal space. Non-native tone speakers tend to also use a narrower pitch range to produce lexical tone distinction. As in perception, production error rates vary from tone to tone.

Differences in the linguistic function of pitch in the first language (L1) may account for perception and production difficulties that non-native tone speakers experience. The fact that native tone speakers were better at perceiving tonal distinction of another tone language than non-native tone speakers (Wayland & Guion, 2004) suggests a general benefit of shared linguistic function of pitch at the phonological level. However, variation in perceptual and production error rates across tones within a tone language additionally implies L1 interference at the phonetic level. For example, acoustic similarity between the rising-falling intonation contour on the rightmost pitch-accented syllable (tonic syllable), commonly used in declarative utterances in English, and the high falling pitch contour of Mandarin tone 4 may explain why this Mandarin tone was identified most accurately on the final syllable (Broselow, Hurtig, & Ringen, 1986). Perceptual focus on pitch height rather than pitch contour among native English listeners may also reflect the importance of pitch height in English intonation and lexical stress. Finally, differences in pitch contours of corresponding tones in Mandarin and Cantonese may explain tonal confusion patterns of Mandarin tones by Cantonese listeners (So & Best, 2010). Thus, L1 transfer at both the phonological and phonetic levels affects non-native perception and production of lexical tones.

Previous research also indicates that tonal discrimination ability improves with experience (Wang, Spence, Jongman, & Sereno, 1999; Wayland & Guion, 2004). Improved perception leads to improved production and vice versa (Leather, 1990; Wang, Jongman, & Sereno, 2003). With training, the ability to integrate and use pitch to identify (pseudo-)words has also been demonstrated (Wong & Perrachione, 2007).

The effects of musical background on perception have also been explored. In general, musical background has a positive impact on the perception of lexical tones. An influence of lexical tone background on musical pitch perception has also been documented. Tone speakers are often (but not always) better than nontone speakers in pitch discrimination. Furthermore, more individuals with absolute pitch are found among native speakers of tone languages. However, the relationship between absolute pitch and lexical tone learning remains unclear.

Pedagogical Implications

Influence of L1 suprasegmental system both at the phonological and phonetic levels is an important consideration in the teaching of a tone language. Native tone speakers learning another tone language may outperform learners from a nontone-language background. However, phonetic differences of corresponding tones in the two tone languages may be an important source of interference. For both groups of learners, attention should be paid to pitch dimensions (height or contour) that are not linguistically contrastive in the L1. Explicit instruction on the entire pitch contour of the target language may prevent learners from paying attention to only pitch dimensions that are linguistically relevant in their L1. Given their mutual and reciprocal benefits, both perceptual and production training using both real words, nonwords (e.g., pure tones, hums), and pseudo-words are encouraged to promote auditory and linguistic levels of perception. In the initial stage of training, the use of nonwords and pseudo-words with familiar L1 sound sequences may allow learners to better focus on pitch patterns of the target language. Training should extend from shorter to longer syllable strings to ensure accuracy in various positions. Using stimuli produced by multiple talkers in various phonetic environments should promote tone normalization ability. Finally, possible effects of the learner's musical background should also be noted. Musicians are auditorily more acute than nonmusicians in pitch perception, but their superior ability to acquire lexical tones has yet to be confirmed.

In summary, our understanding of tone—its linguistic structure, representation, processing, and acquisition—has increased over the years, and research on lexical tone perception and production has yielded valuable insights into the mechanisms underlying the acquisition of tones that can be used to guide and improve the teaching and learning of tones.

Surveys

ELVIS WAGNER

Research involving the use of surveys to collect data has long been prevalent in applied linguistics. Survey research differs from experimental research in that the researcher does not try to manipulate or control the setting or variables being studied (Nunan, 1992; Mackey & Gass, 2005). Rather, the researcher seeks to compile or gather information that usually cannot be observed directly or examined through performance data. Surveys are useful in collecting data that respondents are able to report about themselves, including factual information (e.g., background characteristics, biodata), and behaviors such as habits, personal history, or learning strategies. Survey research is also useful in operationalizing and measuring abstract psychological constructs such as language learner attitudes and beliefs, motivation, and anxiety.

Survey research is usually subdivided into questionnaires and interviews (Brown, 2001). These two types of data collection techniques vary in the mode in which the data are elicited, and also the way in which the participants respond to the elicitation. With questionnaires, the data are usually elicited through written questions or statements that the participants respond to (usually) in writing, while with interviews the elicitation is usually done orally, with the participants also responding orally. Questionnaires can be used to gather data from large numbers of participants relatively quickly and efficiently. For more information about data elicitation involving interviews, see the “Interviews” entry in this volume.

Questionnaires

Questionnaires can be designed to have open-ended or closed-ended responses or a combination of the two. With open-ended questionnaires, the participant responds to a written prompt (a question or a statement) asking for information, an opinion, and so forth. For example, a questionnaire could ask “What is your L1?,” in which a single-word answer is expected, or it could ask, “Why are you learning English?,” in which a much longer answer could be expected. With closed-ended questionnaires, the participant is forced to choose an answer from a list of possible answers. For example, the question “What is your L1?” could have languages listed from which the participant chooses one. For the question, “Why are you learning English?,” the participant has to choose from a number of possible answers, such as “I like to travel,” or “I like to learn languages.”

In general, the type and depth of information that the researcher is seeking dictates the type of questionnaire used. That is, if researchers want to explore an issue in great depth or explain a particular phenomenon, they will often collect large amounts of data from a smaller number of individuals (using open-ended questionnaires or interviews), and usually utilize qualitative data analyses. On the other hand, if researchers want to be able to make claims about the generalizability of the results of the research, they will necessarily have to collect data from a larger number of individuals, which usually requires the use of closed-ended questionnaires and quantitative data analysis techniques. Of course, a survey instrument containing a combination of open-ended and closed-ended items is possible, and often desirable.

In order to make valid inferences from the results of survey research, it is vital that the instruments used for data collection be well designed and validated. The creation of survey instruments is beyond the scope of this entry, but the reader is urged to consult Dornyei and Taguchi (2009) or Brown (2001) for detailed instructions in survey instrument development.

Questionnaires can be self-administered or group-administered. Self-administered questionnaires are usually mailed to respondents, or, increasingly, researchers will e-mail a link to a Web site hosting an electronic questionnaire. These self-administered questionnaires allow individuals to complete them at their convenience. While self-administered questionnaires have the advantage of allowing a large number of participants to be included in the study, they also have the inherent disadvantage of lower response rates, which presents problematic sampling and generalizability issues. Group-administered questionnaires are administered to a group of respondents at the same time, often in classrooms, making administration and completion of the questionnaires more systematic, and usually allow for the researcher to be able to answer questions that respondents might have.

Researchers using questionnaires must use appropriate sampling techniques to ensure the generalizability of the results. The issue of sampling is often neglected in applied linguistics survey research. In order to ensure that the results of the data analysis from the sample of participants is generalizable to the larger population, appropriate probability sampling techniques must be implemented (i.e., random, stratified random, systematic, and cluster sampling) (Perry, 2005; Vogt, 2007).

Scales in Quantitative Survey Data

Much of the applied linguistics research using questionnaires involves the attempt to measure and analyze psychological constructs that are impossible to observe directly. Scaling is the process of creating instruments to measure and quantify these constructs so that statistical analyses can be performed on the data. Data from open-ended questionnaires usually require some sort of qualitative analyses, which is beyond the scope of this entry. Some data from open-ended questionnaires, however, can be quantified. These data would include nominal responses, which would require a coding scheme to then convert the data to a categorical scale. Closed-ended questionnaires might also result in nominal data, if respondents are forced to choose from a list of nominal alternatives. Ordinal scales allow for the things being measured to be rank ordered in comparison to each other. So, for example, test takers might be ranked according to how they scored on the test, with the person scoring the highest ranked first, the next highest score ranked second, and so on. With ordinal scales, the rankings depict the order, but there is no information about the distance between the different points on the scale. In contrast, interval scales are measurement scales in which the points along the scale are at equal distances or intervals no matter where they are located on the scale. Temperature scales such as Fahrenheit or Celsius are examples of interval scales. Similarly, data from language tests are usually perceived as being on an interval scale (although they are probably not truly equal interval scales). Ratio scales are interval scales in which the “zero” on the scale indicates a total absence of the variable being measured (Kelvin is an example of a temperature ratio scale).

In applied linguistics survey research using closed-ended questionnaire items, Likert items are most commonly used. Likert items involve a statement, and the respondent has to choose a response to that statement from a number of choices. Often there are five choices: *strongly disagree*, *disagree*, *no opinion/don't know*, *agree*, *strongly agree*. However, respondents have a tendency to bunch their responses toward the middle of the scale, and so Likert items with seven or even nine choices are also common, in an attempt to ensure

more variance in the measurement. Alternatively, researchers sometimes create Likert items in which the neutral item (the *no opinion/don't know* option) is excluded, in order to force respondents to choose a response, again in an attempt to avoid central tendency bias, and to ensure more variance in the measurement.

Usually multiple Likert items will be used to measure the same construct or dimension of that construct. These multiple items are designed to be very highly related to each other, and use slightly different wording to make essentially the same statement that the respondent must respond to. The sum of these multiple Likert items are then considered to be a scale or subscale of the construct being measured. This is a summative scale. To use a common example from applied linguistics research, a questionnaire composed of a series of Likert items might be administered to a group of learners asking them about their level of anxiety related to language learning. This overall questionnaire might consist of a number of smaller subscales (e.g., language test anxiety, language classroom anxiety, language speaking anxiety). There might be three or more Likert items related to each of the smaller subscales or dimensions of the overall construct of anxiety.

Summing (and averaging) responses from Likert items to create a scale or subscale is done for a number of reasons. The reliability of measurement of a particular unidimensional construct will be higher if several items are used rather than a single item. In addition, creating a summative scale allows for the researcher to treat the data as interval data, and parametric analyses can subsequently be conducted on the data. Measurement experts debate whether an individual Likert item should be considered interval data, because it is unlikely that respondents necessarily perceive the five different responses as equidistant (on an interval scale) (Vogt, 2007). However, the treatment of summative Likert scale data as interval data is less problematic, and is commonly done in applied linguistics research.

Other types of scales used in survey research include cumulative scales (sometimes referred to as Guttman scales) and semantic differential scales (see Dornyei & Taguchi, 2009, for more information about the different types of scales commonly used in applied linguistics survey research).

Analysis of Questionnaire Data

For nominal or categorical questionnaire data, the response data are usually tabulated. The appropriate measure of central tendency would be the mode. In order to make comparisons, the chi-square test would be used. For correlation, biserial or point-biserial correlations would be used to correlate categorical data with interval data. For individual questionnaire items using an ordinal scale (e.g., an individual Likert item), because the data are technically ordinal the most appropriate measure of central tendency would be the median, although the mean is often used. For correlations involving ordinal data, Spearman's rank correlation coefficient should be used.

For Likert item questionnaire data, the multiple items measuring each specific dimension of a construct can be combined to create summative scales or subscales. A numerical score is used to correspond to the responses. On a 5-point Likert scale, *strongly agree* is replaced by a 5, *agree* is replaced with a 4, and so on. The scores for all of the items in the summative scale are combined, and the data can then be considered interval data. It is recommended that at least three items be used to create a summative scale. If an item (or more than one item) in the summative scale is negatively worded, it is vital to ensure that the item is reverse-coded during the data preparation stage. If the summative scale data are normally distributed, then parametric data analyses can be conducted with the data.

To ensure that all of the individual items in a summative scale are indeed measuring the same construct, a reliability analysis is necessary, usually using Cronbach's alpha. If the alpha is sufficiently high (Vogt, 2007, calls for a minimum of .70), then there is evidence

that the individual items are all reliably measuring the same construct, and a summative scale would seem appropriate; parametric data analyses can be conducted on the data and group comparisons made. It is important to realize that, depending on how the questionnaire is constructed, it might not be appropriate to estimate the internal consistency reliability of the overall instrument. That is, if the questionnaire is designed to measure a number of different constructs, then a reliability analysis for each summative scale is necessary. If the questionnaire involves a large number of individual items, and is administered to a large number of respondents, then factor analysis can be conducted on the data to ensure the reliability of the individual items.

Critiques of Survey Data

One of the major criticisms of survey research focuses on the validity of using questionnaires to measure an abstract, unobservable, psychological construct (e.g., anxiety). These types of constructs are multidimensional and inconstant abstractions (Dornyei, 2001), yet researchers are forced to try to measure them using only a relatively small number of statements or questions that a participant has to respond to.

This problem is compounded in applied linguistics research by the fact that respondents are often required to read and respond to the statements in their second language. There is always concern about the extent to which the respondents truly understand the statements that they are required to respond to. Obviously, the language in L2 questionnaires should be as simple and straightforward as possible, but again this is difficult to implement when trying to operationalize and measure abstract psychological constructs. An alternative is to translate the questionnaire into the respondents' first language, but this is often more feasible in a foreign language context than in a second language context. Variation in translation also entails threats to the validity of the results. One way to address these issues is through the use of back translation. Here the instrument is translated into the L1 of the participants, and then a different translator (or translators) translates the L2 instrument back into the L1, in order to investigate how closely the back-translated instrument corresponds with the original instrument.

Another critique of survey research utilizing interviews and questionnaire data involves how reliably the construct is being measured. Time constraints, language considerations, and interviewers' and respondents' attitudes and level of motivation, fatigue, and tolerance all affect reliability of measurement. In general, the more items a survey instrument has, the more reliable it tends to be, but there is a cut-off point where adding more items becomes counterproductive. Respondents can quickly become fatigued and less tolerant to responding to questions (especially in an L2), and so researchers must carefully consider how many items to include on survey instruments. In addition, writing effective survey questions is not an easy task, and poorly developed questionnaire items or interview schedules often create threats to reliability with survey research data (Wagner, 2010).

Conclusion

Survey research involving interviews and questionnaires has a long history in applied linguistics research, and our understanding of language learners' attitudes, beliefs, anxieties, motivation, and strategies has benefited greatly from the research involving survey methodology. Although the research has been criticized in a number of areas as described above, it is also important to note that most of these critiques relate to shortcomings in how the research was conducted, rather than the research methods themselves. Because of the need to investigate internal, usually affective variables that cannot be observed

directly or examined through performance data, survey research has played and continues to play a vital role in the advancement of the field.

Svartvik, Jan

HANS LINDQUIST

Jan Svartvik (b.1931) studied at Uppsala University, Duke University, and the University of Durham. After receiving his licentiate from Uppsala University in 1961 he spent four years as a research assistant and later assistant director at the Survey of English Usage at University College London. He received his doctorate from Uppsala in 1966 and was a lecturer at Gothenburg University before he was appointed to the chair of English at Lund University, which he held from 1970 to 1995. He has received doctor *honoris causa* degrees from the University of Bergen, Masaryk University, Brno, and the University of Helsinki.

Early Work: Prosody, Grammar, and Elicitation Tests

During his four years at the Survey of English Usage at University College in the early 1960s, under the directorship of Randolph Quirk and with colleagues such as Sidney Greenbaum and Geoffrey Leech, Svartvik was introduced to the principles of collecting and analyzing corpora of both spoken and written English. One publication that he co-authored at this time (Quirk, Duckworth, Rusiecki, Svartvik, & Colin, 1964) was a study of the correspondence of prosodic to grammatical features in English—an early sign of the interest in the spoken language which has been a strong element throughout his career, as well as a first indication of his zest for using computers in linguistic research.

Although corpus work was central to the studies carried out at the Survey of English Usage, it was supplemented with elicitation tests with native speakers in order to access information which was not available in corpora. Quirk and Svartvik (1966) use three types of elicitation tests to investigate degrees and kinds of acceptability—judgment tests, operation tests, and selection tests. The starting-point was the Chomskyan idea that the fundamental aim of grammar is to account for “all and only the grammatical sentences of a language” (Chomsky, 1957, p. 13, 21, quoted in Quirk & Svartvik, 1966, p. 9). One of the most important conclusions of the study, however, was that the results indicated that “clear-cut categorization is futile and may actually inhibit our understanding of the nature of linguistic acceptability” (p. 99). The authors also found that gradience persisted in grammatical as well as lexical acceptability (p. 100). Gradience was to remain an important notion in Svartvik’s descriptive work in grammar.

Description and Theory: The Passive

Svartvik’s doctoral dissertation, *On Voice in the English Verb* (1966), also starts out with a reference to Chomsky and in particular to the interest in the passive shown by generative linguists, the “passive transformation” being one of the prototypical transformations. Svartvik, however, points out that his aim is not primarily theoretical, but rather to provide an adequate corpus-based *description* of the phenomenon of voice in English. After analyzing a corpus of 323,000 words of spoken and written British English from 1950 to 1964, he proposes that there is a “passive scale” from types with a clear relationship between active and passive clauses to those where the passive is better seen as a clause type in its own

right. He found a low proportion of passives with *by*-agents and identified a number of lexical restrictions on the verbs in passive constructions. He was thus able to show that results from a corpus study had obvious relevance also for theoretical discussions.

Corpus Building

In 1975, after returning to Sweden, Svartvik embarked on a new major corpus project. The spoken component of the Survey of English Usage had originally been transcribed on slips that were kept in filing cabinets at University College London. In order for this treasure to be made available to all interested scholars, Svartvik and a team of colleagues began work on transferring the transcriptions onto computer tape to create the London–Lund Corpus of Spoken English. For a long time the resulting electronic corpus of approximately half-a-million words remained the biggest corpus of spoken English and it has been used for many groundbreaking studies of spoken discourse. One third of the corpus (170,000 words) was also published in book form (Svartvik & Quirk, 1980). The corpus and research carried out on it are described in Svartvik (1990).

Grammar Writing

One of the outcomes of the research carried out on the Survey of English Usage material was the writing of *A Grammar of Contemporary English* (GCE) by Quirk, Greenbaum, Leech, and Svartvik (1972), where Svartvik was the only non-native linguist among the four authors. Although not strictly corpus-based, the book used some corpus data and was considered the leading reference grammar at the time.

The GCE had several spin-offs, one of which was *A Communicative Grammar of English* (Leech & Svartvik, 1975). This innovative grammar book was inspired by developments in communicative language teaching and by the Hallidayan functional approach to language. Its main part is not organized according to linguistic structures, but under four main kinds of *meanings*: “Concepts,” “Information, reality and belief,” “Mood, emotion and attitude,” and “Meanings in connected discourse.” Under the subheading “Influencing people,” for instance, there are sections “Commands,” “Requests,” “Advice, suggestions and invitations,” and “Warnings, promises and threats.” Although never a mainstream text, the grammar has been constantly in print and came out in a third edition in 2003. Svartvik has also cowritten best-selling contrastive grammars for the Swedish secondary school (Svartvik & Sager, 1971) and for Swedish universities (Svartvik & Sager, 1978).

In 1985, the four authors of the GCE published a totally new and much larger reference grammar, *A Comprehensive Grammar of the English Language* (Quirk, Greenbaum, Leech, & Svartvik, 1985). This magnum opus is still corpus-informed rather than corpus-based. Prominent features behind the analyses in the grammar are concepts such as gradience, scales, clines, and indeterminacy which sometimes lead to alternative analyses. Criticized by some for alleged instances of terminological ambiguity and vacillation, it is still the most comprehensive description of present-day English and as such remains a major reference point for studies of the English language.

Promotion of Corpus Linguistics and Applied Linguistics

Jan Svartvik was one of the founding fathers of the International Computer Archive of Modern and Medieval English (ICAME) and has remained an active promotor of corpus linguistics in many different capacities. In Svartvik (1992, pp. 8–10) he presented the

advantages of corpus linguistics in a preface to a collection of papers that he edited. His arguments are given here in abbreviated form:

- Corpus data are more objective than data based on introspection.
- Corpus data can easily be verified by other researchers and researchers can share the same data instead of always compiling their own.
- Corpus data are needed for studies of variation between dialects, registers and styles.
- Corpus data provide the frequency of occurrence of linguistic items.
- Corpus data do not only provide illustrative examples, but are a theoretical resource.
- Corpus data give essential information for a number of applied areas, such as language teaching and language technology (machine translation, speech synthesis, etc.).
- Corpora provide the possibility of total accountability of linguistic features—the analyst should account for everything in the data, not just selected features.
- Computerized corpora give researchers all over the world access to the data.
- Corpus data are ideal for non-native speakers of the language.

However, he points out that it is crucial that the corpus linguist engages in careful manual analysis as well. Total accountability and close attention to the data is characteristic of Svartvik's work as a descriptive linguist and grammar-writer. All through his work, from his dissertation on the passive in English and onwards, he has also stressed that corpus work has a bearing on theory.

Svartvik was vice-president in 1978–81 and president in 1981–4 of the International Association of Applied Linguistics (AILA), and in 1981 he organized the Sixth International Congress of Applied Linguistics (AILA 81) in Lund. He has served on many national and international committees on various aspects of corpus linguistics, applied linguistics and the teaching of languages in schools and universities. He has been the coeditor of several collections of papers and book series, and a member of the editorial board of a number of scholarly journals.

Computational Linguistics and Applied Corpus Linguistics

Apart from the rather obvious case of using data from corpus analyses in the writing of reference works and pedagogical grammars, there are other applications of corpus methodology. In the mid-1960s, Svartvik was asked to make a linguistic analysis of a number of statements made by Timothy John Evans, who had been hanged in London for the murder of his wife and daughter in 1950 but was believed by many to be innocent. He made a statistical analysis of sentence and clause length, clause linkage and nonstandard language in the statements and found some support for Evans's claim that certain parts of his statements were true and others were not (Svartvik, 1968, pp. 45–6). In October 1966, Evans was granted a posthumous free pardon. Svartvik does not claim any credit for the pardon, but he has been given the credit for coining the term “forensic linguistics” in the process.

Svartvik also applied computer techniques to theoretically interesting linguistic problems. In Carvell and Svartvik (1969), the authors used a computer program primarily intended for the classification of bacteria in order to develop automatic methods for classifying linguistic data. The corpus consisted of 10,000 words from the Survey of English Usage. Just like Svartvik (1966), they found the concept of gradience to be relevant, since their results showed a few fairly distinct classes with some partially overlapping ones.

Another innovative venture which combined theory and computational application was the Text Segmentation for Speech (TESS) project, which was begun in 1983 and sprang

out of the work with the London–Lund Corpus (Svartvik, 1984). This was an early Natural Language Processing (NLP) project aiming at investigating how natural speech is segmented or chunked into “tone units” and at developing theories that predict English intonation in order to improve automatic text-to-speech systems.

Popular Writing

After his retirement in 1995, Svartvik used his pedagogical skill and mastery of many aspects of the English language to write a number of popular handbooks for the Swedish and the international markets. His entertaining book on the history and development of the English language (Svartvik, 1999) won the Swedish August prize (named for August Strindberg) for “Swedish non-fiction book of the year” and was later rewritten in an English version (Svartvik & Leech, 2006). Together with his son Rikard he wrote two useful handbooks for Swedish users of English (Svartvik & Svartvik, 2001, 2004), which have been translated into several other languages.

Conclusion

Svartvik’s work is characterized by a strong interest in the intricacies of the English language and a desire to produce correct descriptions of its minute details—to get the facts right. Although not a theory builder, he has always been aware of ongoing theoretical discussions, being inspired by them and producing work that feeds into them. He has played an important role in developing and promoting corpus linguistics. Another prominent aspect of his work is his pedagogical zeal, which has led him to writing handbooks for schools, universities, and the general public in Sweden and abroad as well as contributing frequently to the pedagogical debate. A third feature is an interest in technology, which facilitated cooperation with computer specialists and the development of technical solutions in dealing with especially transcribed spoken data. Finally, Svartvik’s love for language can be detected in his lucid writing style and in his famous after dinner speeches at ICAME conferences and other gatherings.

Swain, Merrill

SHARON LAPKIN

Merrill Swain (1944–) has made multiple scholarly contributions to the field of applied linguistics. Her prolific and groundbreaking research can be categorized under three main headings: (a) immersion education; (b) output, collaborative dialogue, and languaging; and (c) testing and assessment.

Immersion Education

Swain's name is virtually synonymous with immersion education in Canada. Building on the evaluation of the first immersion program in Canada (Lambert & Tucker, 1972), Swain's extensive immersion program evaluations in at least six school districts in Ontario, followed later by similar evaluation studies in other parts of Canada, ensured that the findings from these large-scale studies would be generalizable; in fact, there was a great deal of consistency in results across evaluations of specific immersion program models, in large part because of the care taken in the design of the component studies. Thus, cohorts of students within each school district were matched as closely as possible with comparison groups, they were followed longitudinally as they progressed through the grades, and new cohorts were also assessed to allow for cross-sectional comparison.

The research questions centered on immersion students' achievement in French, first language (in the early years that language was always English), and academic subjects such as science. The possible cognitive impact of studying through a second language was also measured, using mainly intelligence tests. The findings were reassuring, establishing that immersion students learned content material to the levels of comparison groups, that progress in their home language kept pace (and sometimes overtook) that of their regular English program peers, that their levels of French proficiency far exceeded what was possible in "traditional" French second language programs, and that any cognitive effects were neutral or positive. From the beginning, although the mandate was to conduct large-scale quantitative evaluation studies, Swain supplemented these with careful, qualitative explorations of second language acquisition by immersion students, the nature of immersion student talk and writing, and the integration of language and content teaching in immersion classrooms, among others (e.g., Swain, 2000a).

In 1997, Swain and Johnson discussed immersion education as a category within bilingual education from an international perspective, defining its key characteristics. Swain and Lapkin (2005) revisited these core features of the prototypical immersion program in the Canadian context, in light of the changing demographics of the society. Thus, for example, the core feature specifying that the L2 is the medium of instruction in immersion programs was reformulated to read "the immersion language is the medium of instruction" to accommodate the fact that many students enrolling in immersion speak immigrant languages at home. A second feature, that immersion aims for additive bilingualism, could be taken for granted in the first decade or two of immersion education in Canada when immersion students were all Anglophones; in 2005 it became important to state that maintaining the additive nature of immersion meant that the home languages of the diverse immersion student population had to be supported at school so that immersion would not become a subtractive environment.

The “laboratory” nature of immersion programs early in their development meant that they provided an ideal context for examining second language learning in a relatively controlled environment. Swain’s nuanced understanding of the unique nature of immersion gave rise to the construct she is perhaps most famous for, that of output.

Output, Collaborative Dialogue, and Languageing

A chronological reading of Swain’s writings on the construct of output is instructive. In 1985, she reacted to Krashen’s (1985) input hypothesis as inadequate to account for learning in an immersion context; in other words, input alone, she felt, could not explain the acquisition of the target language. Immersion students reached advanced levels of listening and reading comprehension, but their language production (speaking and writing) remained inaccurate in spite of large quantities of comprehensible input. Swain argued that immersion learners had too few opportunities to produce French and were not being systematically “pushed” in their output. Comprehensible output, one step beyond learners’ current interlanguage, was as central to L2 learning as comprehensible input.

Building on this early work, Swain (1995) posited three functions of output: (a) noticing (raising awareness about gaps in students’ knowledge of the L2); (b) hypothesis testing (language production triggers feedback on the language they generate, which often prompts learners to modify their output and to learn); and (c) the metalinguistic function (where learners reflect on language consciously). Swain (1995) concluded by introducing the Vygotskian idea that learning occurs during social activity, specifically dialogue where students solve problems they encounter in their language learning. This collaborative dialogue (Swain, 2000b), entailing problem solving and knowledge building can be examined for “learning in progress”; in fact collaborative dialogue mediates these processes. In Swain (2000b), “output has been extended to include its operation as a socially constructed cognitive tool” (p. 112) and Swain explicitly embraces sociocultural theory of mind as an explanatory framework for learning, including L2 learning.

Revisiting the construct of comprehensible output, Swain (2005) explained that output is both product and process, and emphasizing that “the activity of producing the target language” (p. 474) is key in moving learners from semantic to syntactic processing and to reflecting on their language use. She discusses the complementary nature of information processing and sociocultural theoretical approaches to L2 learning, suggesting that the latter “puts language production in a ‘star role’”: “Speaking (and writing) are conceived of as cognitive tools—tools that mediate internalization; and that externalize internal psychological activity . . . tools that construct and deconstruct knowledge; and tools that regulate and are regulated by human agency” (p. 480).

Her quest to capture the dynamic nature of output led Swain (2006a) to coin a new construct, namely languageing. She suggested that speaking and writing are “tools of the mind, mediating the cognition and re-cognition of experience and knowledge” (p. 106). Languageing is a form of shared cognition, made visible when learners talk through cognitively complex problems. Languageing implies learner agency and provides learners with a cognitive and affective tool as they construct meaning, together (i.e., collaborative dialogue) or individually.

Testing and Assessment

Swain’s contributions to testing and assessment began with the seminal paper coauthored with Michael Canale in 1980, “Theoretical bases of communication approaches to second language teaching and testing.” In that article, components of proficiency (grammatical,

sociolinguistic, strategic) in a second language are identified and rationalized. Shortly thereafter, Canale (1983) added discourse competence to the framework, and the framework was used as the basis for a large-scale project intended to validate these four constructs statistically. In a 1983 publication, Swain illustrated how a testing unit developed for grade 9 French immersion and based on this framework was highly communicative in nature. She articulated four principles of communicative language test development: “start from somewhere” (basing a test on sound theoretical principles), “concentrate on content” (ensure that the content was motivating, substantive, integrated around a theme, and interactive), “bias for best” (elicit the learner’s best performance by providing clear instructions, adequate time and access to aids such as dictionaries), and “work for washback” (provide extensive information to teachers who administer the testing unit, so that the nature of the test will influence pedagogy).

A decade later, when the statistical exploration of results from a battery of communicative language tests (including the one referred to above) had yielded low internal reliabilities, Swain (1993) asked, with respect to second language testing, “Is there a conflict with traditional psychometrics?” In fact, she argued convincingly that low levels of internal consistency indicate the complexity of second language proficiency and that traditional testing theory was incompatible with the variation one would expect in communicative language behavior.

In keeping with her growing interest in a sociocultural theory of mind as a theoretical lens, Swain (2001) turned her attention to what might be learned by examining dialogue between learners. Learners are less anxious in group testing than they are in individual test situations, thus helping to “bias for best.” Learners co-construct knowledge as they interact, and learner dialogues also enhance our understanding of their cognitive and strategic processes and allow us to witness learning in progress. Thus, “the content of the dialogues of test-takers could provide test-developers with targets for measurement” (p. 297).

Finally, in a chapter that explores the complementary contributions of information processing and sociocultural theory of mind perspectives, Swain (2006b) asks “What does it mean for research to use speaking as a data collection tool?” She argues that verbal protocols collected as learners take language tests, often by means of stimulated recall, actually change or improve learner performance. Reflecting aloud on or “languaging” their performance enables learners to “talk through” their language learning problems; that talk mediates and enhances their learning.

Final Comment

Ultimately, Swain’s greatest contribution to applied linguistics may lie in the gift she has for making complex concepts accessible to multiple audiences—theoreticians, second-language researchers, teachers, and learners alike. This talent is highlighted in the recent volume by Swain, Kinnear, and Steinman, wherein learner narratives exemplify key concepts in sociocultural theory as it relates to second language learning.

Swales, John M.

BETTY SAMRAJ

Perhaps most widely known for the create-a-research-space (CARS) model to account for the rhetorical structure of research article introductions, John M. Swales has made an indelible mark on English for specific purposes (ESP) through his many discourse studies of academic genres and by the significance of his publications on the relationship of linguistic research to the teaching of English for academic purposes (EAP), the role of English in the research world, and materials development for advanced academic writing. His research covers three main areas: genre analysis in terms of rhetorical moves, corpus linguistics, and pedagogical matters including materials development, EAP course development, and broader issues such as the role of English in the academic world.

Swales's career in English-language teaching (ELT) began in Italy and Sweden in the early 1960s where he taught a variety of students including young researchers, elementary schoolchildren, and housewives, and was followed by a teaching stint in a Libyan university. Following a graduate diploma in ELT and Linguistics at Leeds University, Swales's rich career in ELT continued in Libya, the UK, and Sudan, characterized by materials development, teacher training, and publications in ESP. A faculty position at Aston University was the site for some of his early important research. Swales then served both as the director of the English Language Institute and a professor of linguistics at the University of Michigan, from which he retired in 2006. During this period he also served as coeditor of the international journal, *English for Specific Purposes*.

Genre Analysis

Swales's early work on research article introductions gave rise to the CARS model (1990a), where the structure of this part-genre is accounted for in terms of three rhetorical moves, establishing a territory, establishing a niche, and occupying the niche, and their constituent steps. Further studies on research article introductions in different languages and disciplines inspired by the CARS model led to a revision of this model in Swales's (2004) recent book, *Research Genres*, where the three-move structure is preserved but with some changes made to the constituent steps. Swales and other EAP scholars have continued research on the structure of other sections of the research article and other academic genres, such as the submission letter, grant proposal, and PhD defense, in terms of rhetorical moves, building on the form–function relationship that underpins the CARS model.

Swales has also conducted valuable work on discourse features such as the use of citations and imperatives, which has added another layer to our understanding of academic discourse. His early work on citations (Swales, 1986), drawing on different fields such as the sociology of science and rhetoric, is a good example of the benefits of the interdisciplinary perspective that often underlies his research. It is therefore not very surprising that Swales's research itself has had wide-ranging effects on other specializations, such as computational linguistics (Teufel & Moens, 2002).

Perhaps even more important than the number of descriptive studies on academic genres that have ensued from Swales's CARS research are the concepts—genre, communicative purpose, rhetorical move, and discourse community—that Swales's work has established

as key in the field of applied linguistics in general and ESP work in particular. One of the first mentions of the notion of genre in applied linguistics research was in Swales's work on research article introductions in 1981 (see also 2001a, p. 47). Swales (1990a) provides an extensive discussion of the concept in his book *Genre Analysis*, tracing its use in various other fields such as rhetoric and folk studies, and arrives at a working definition of genre (p. 58). This comprehensive treatment of the concept has led to literally hundreds of EAP studies. Over time, it has been expanded to include relationships amongst genres, such as genre networks, sets, and chains, which Swales synthesizes and reflects on in *Research Genres* (2004). Swales (1996) also introduces the notion of occluded genres, which are genres hidden from public view, such as evaluation letters for tenure and promotion, and notes that these can therefore prove challenging for novices in an academic community.

In his original theory of genre, Swales (1990a) posits a clear relationship between communicative purpose, genre, and its structure. However, the privileged role played by communicative purpose in a text's genre categorization is problematized and a more nuanced role is argued for instead in his later work because the communicative purpose for a text may not be obvious on the outset and may not even be agreed upon by a group of experts (Askehave & Swales, 2001; Swales, 2004). Another major contribution of Swales's work in genre analysis has been the rhetorical move framework, which is related to the notion of communicative purpose. Swales (2004, pp. 228–9) defines a move as a "discoursal or rhetorical unit that performs a coherent communicative function" in written or spoken discourse and descriptions of genres in terms of moves and their constituent steps have played an important role in exploring issues such as genre relatedness, genre evolution, and genre variation.

Another key component in Swales's genre theory is the discourse community in which genres are produced and consumed. Subsequent genre-based studies have revealed that discourses are not always produced in monolithic discourse communities but communities of practice bounded by disciplinary and cultural values. Following a problematization of the concept of discourse community, the notion of a place discourse community is developed in Swales's (1998, p. 204) *Other Floors, Other Voices*, a textography of three communities of practice: a computing resource site, a university herbarium, and an English language institute, situated in a building at the University of Michigan. Mostly through a thick description of discursive practices in these three sites, he concludes that two of these can be given the status of a place discourse community.

Corpus Analysis

Swales's more recent research employing corpus techniques focusing on sentence level features may first appear to be a shift from Swalesian genre analysis. However, a consideration of his work before his CARS fame reveals that Swales had an early interest in characterizing the grammatical features of specialized discourses, such as verb frequency in scientific English. A number of his corpus-based studies are based on the *Michigan Corpus of Spoken Academic English* (<http://micase.elicorpora.info>), a corpus he was instrumental in creating. An example is a study of the metatextual uses of *thing* and *point* in various speech genres (Swales, 2001b). He concludes, among other things, that the use of *point* can vary in its metatextual function depending on whether the genre is monologic or dialogic. A recent coauthored study (Wulff, Swales, & Keller, 2009) based on a specialized corpus of conference presentations and discussions, *The John Swales Conference Corpus*, explores phraseological choices in the presentations and discussions, the characteristics of the chairs' discourse, and the nature of humor in the presentations and discussions, leading to the conclusion that presentations include more features of empiricist repertoires than

the ensuing discussions.

Materials Development and ELT

Swales's impact on the field of EAP has not only been through his extensive descriptive studies of academic discourses but also through influential EAP textbooks produced over the last 40 years. Swales's devotion to materials development in his early years of teaching in Europe and the Middle East comes through quite clearly in the stories recounted in his memoir, *Incidents in an Educational Life* (Swales, 2009a). One of Swales's earliest ESP textbooks, *Writing Scientific English* (1971), which sold more than 50,000 copies, includes these early materials that were created to meet the specific needs of his students. His more recent EAP textbooks coauthored with Chris Feak (such as Swales & Feak, 2004) draw on our understanding of the rhetorical organization and linguistic attributes of key academic genres. In addition, these pedagogical materials reflect the teaching philosophy held by Swales and other key EAP scholar-practitioners, which includes raising the discourse consciousness of junior scholars and graduate student writers, acknowledging the variation in the discourse practices of different disciplinary communities, and engaging students in discourse-based tasks leading to the production of key genres.

Beyond producing EAP materials, Swales has also contributed significantly to the theory–practice interface by explicitly discussing various parameters in the teaching of EAP, and not dismissing problematic or uncomfortable aspects of this enterprise. Swales was an early proponent of the use of discourse analysis in teaching (Swales, 1990b) and believed in the value of explicit teaching. In addition, Swales has used his vast knowledge of the field and varied experiences around the globe to provide insights on the field of ELT as a whole. He has remarked on the growth of ELT as an “intellectual, educational, and commercial activity” (1993, p. 290) while at the same time noting the poor remuneration given to ESL lecturers in US universities. Questions on the role that ESP teaching has played in the demise of academic registers in other languages such as Swedish and German, although unusual to be raised by someone whose career is closely tied to the field, have been thoughtfully discussed (Swales, 1997).

Also important for the field of ELT in general and ESP in particular have been the publications detailing not just successes in applying the results of discourse research to the development of EAP courses and teaching activities but also cases where such endeavors have been met with less than complete success. A success story Swales and his coauthors (Swales, Barks, Ostermann, & Simpson, 2001) discuss concerns the construction of a graduate-level EAP course for Architecture students based on analysis of videotapes of a key academic speech event in the discipline, the final critique, and the sorts of literacy events assigned in the Master's Architecture program, as well as interviews with instructors and students. This paper usefully shows how macro- and micro-analyses of both successful and unsuccessful student productions can be applied to EAP course design. An example of a less successful materials development experience is found in a paper titled, “Integrated and Fragmented Worlds: EAP Materials and Corpus Linguistics.” Here he describes a number of different tasks he created for advanced students in an EAP course, drawing on corpus studies he conducted, but evaluates them as an “educational failure” and a “discourse analytic shot in the dark” (Swales, 2002, p. 162) and posits reasons for this.

Another area of pedagogical challenge Swales addresses is the issue of the difficulty of finding suitable texts for EAP instruction, an issue not openly addressed in the EAP literature, as he points out. Swales (2009b) analyzes his experiences of materials development and, in particular, carefully describes drafts of a student's literature review that he constructed to be used in tasks used for teaching the writing of the literature review. He

uses these materials to argue for the creative production of materials by EAP instructors when the perfect text is difficult to locate. What is also exemplary about this piece is the generosity with which these materials are offered in this article for others to use in their own classes.

Two important features about Swales's professional career are evident from this overview of his contributions to ESP. First, as we review the arc of Swales's academic career, an interesting pattern, admittedly with some simplification, emerges. His was a career that began with the teaching of English where materials development played an important role, which was followed by extensive descriptive studies of academic discourse, which then ultimately led to further materials development as seen in the EAP textbooks coauthored with Chris Feak. A second noteworthy point about Swales's research development is that, although new areas of research have been added such as corpus studies of oral academic language, Swales has not left original areas of investigation such as genre analysis of academic writing. In fact, his research career is not one of linear movement from one area to another but rather one of integration of new areas to other earlier areas of research.

Syllables

JULI CEBRIAN

A unit of phonology intermediate in scope between the segment and the word, the syllable is a familiar concept among linguists and nonlinguists, and a useful unit of analysis in the description of sound systems and phonological phenomena, even if its relevance beyond its descriptive role is sometimes questioned.

In most languages it is not difficult to tell the number of syllables in a word or a phrase. There would be little dispute among English speakers that the words *brown*, *napkin*, and *intercontinental* consist of one, two, and six syllables, respectively. These speakers would probably agree that the two syllables in *napkin* are 'nap' and 'kin.' The ease with which syllables can be counted is often used as an argument for the validity of the syllable as a phonological constituent. Another argument comes from syllabaries, that is, writing systems where characters designate syllables rather than individual sounds, such as those of the Iroquois language Cherokee, the Liberian language Vai, and the Tibeto-Burman language Yi (Trager, 1972; Rogers, 2005).

Syllabic units also serve as benchmarks for descriptions of the development of child language. Around five to seven months of age, baby noises start to resemble adult speech sounds appearing in sequences of syllables such as reduplicative babbling (e.g., [babababa]), or variegated babbling (e.g., [badadomi]) (Oller, 1980). At this stage in language development, then, the syllable appears to be present as a unit of phonological organization (Vihman, 1992). Further, experimental studies provide evidence for the role of the syllable in speech segmentation and language production, although results vary depending on the clarity of syllable boundaries and the experimental task (e.g., Mehler, Dommergues, Frauenfelder, & Seguí, 1981; Mattys & Melhorn, 2005; among others).

Syllables also play an important role in poetry, where the number or type of syllables, or both, in a verse define the type of meter or rhythmic structure of that verse. In some languages, like Spanish and French, meter is determined by the number of syllables in a line, while in other languages the type of meter depends on the distribution of stressed (or prominent) and unstressed syllables, as in English.

Defining the Syllable

The fact that counting syllables is relatively easy may suggest that syllables are easy to define. However, a satisfactory definition of the syllable has not yet been found. One approach to describing syllables is to examine what is necessarily present in one. If we reexamine the words *brown* and *napkin*, we can say that these words have one and two syllables, respectively, because they contain one and two vowel sounds, that is, the 'ow' in *brown* and the 'a' and 'i' in *napkin*.

There is then a difference between consonants and vowels that makes vowels stand out and signal a separate syllable. This difference has been explained in terms of a property of speech sounds known as sonority. Vowels are the most sonorous sounds and as such they constitute peaks in sonority amid the less sonorous consonants. However, what sonority exactly means is not entirely well understood. For example, sonority has been said to refer to the intensity (or loudness) of sounds relative to that of other sounds with similar

2 SYLLABLES

Table 1 The sonority scale

<i>Manner category</i>	<i>Sounds</i>	<i>Sonority</i>
Vowels	[a, i, ʌ, o, u]	6
Glides	[j, w]	5
Liquids	[l, r]	4
Nasals	[m, n, ŋ]	3
Fricatives and affricates	[s, f, ʃ, ʒ, θ]	2
Stops	[b, g, t, k, c]	1

degrees of stress, pitch, and duration (Ladefoged, 2001), or as the ability of some sounds to make certain types of cavities resonate (Spencer, 1996; Clements, 2009). For example, Spencer explains that vowels, glides (like [j] and [w], the initial sounds in *yellow* and *wine*, respectively), approximants (like [l] and [r]), and nasals (like [n] and [m]) are sonorant sounds because when they are produced some part of the vocal tract is made to resonate. The remaining sounds, fricatives (like [s]), affricates (like the first and last sound in *change*), and stops (like [p], [d], [k]), are not sonorants but obstruents, because they are articulated with friction or a sudden burst of sound within the vocal tract without much resonance.

Regardless of the definition of sonority, there is general consensus among phoneticians and phonologists that sounds can be arranged on a scale from most to least sonorous in what is known as the sonority hierarchy or scale. There are different versions of the scale which vary with respect to the number of distinctions considered, but a generally accepted arrangement is the one given in Table 1, adapted from Selkirk (1984). At the most sonorous end we find the vowels, with low vowels such as [a] being more sonorous than high vowels like [i], followed by glides. Among the consonants, [l] is the most sonorous, nasal sounds are next, and fricatives and stops are found at the low end of the scale. Within each manner category, differences in sonority between voiced (more sonorous) and voiceless sounds or among different places of articulation have also been distinguished (e.g., Ladefoged, 2001).

Sonority does not simply determine what the syllable peak is; differences in sonority among consonants play a role in their distribution. When more than one consonant precedes or follows the peak, the general tendency is for the sonority of the consonants to decrease the further they are from the vowel. This is what is referred to as the sonority principle, also known by other terms such as the sonority sequencing generalization (SSG) (Selkirk, 1984).

Figure 1 illustrates the degrees of sonority of the sounds in the English words *magic*, *thrilled*, and *fact*, following the numerical index given in Table 1. The two sonority peaks in *magic* are the vowels 'a' and 'i', which are surrounded by less sonorous sounds, indicating that the word has two syllables. The word *thrilled* exemplifies a syllable with two consonants preceding and following the vowel. In both cases, the consonant that is closer to the vowel is of greater sonority than the consonant at the edge, supporting the SSG. Finally, in *fact* we find two consonants of equal sonority at the end, a characteristic that has yielded modifications to the SSG that include the possibility of a sonority plateau (see Clements, 1990). Every word has as many syllables as peaks.

Vowels are the most common segments to occupy a peak position crosslinguistically, but consonants are also possible. Consider the English words *label* and *sudden*, commonly pronounced without an intervening vowel between the 'b' and the 'l' and the 'd' and the 'n', respectively. According to the SSG, given the sequencing in *label*, the vowel 'a' (/eɪ/), the stop /b/, and the lateral /l/ cannot be part of the same syllable and thus the two

Figure 1 Sonority peaks in the words *magic*, *thrilled*, and *fact*

Figure 2 Sonority peaks in *label* and *sudden*

peaks in *label* correspond to two different syllables. This is illustrated in Figure 2. Consonants like the 'l' and 'n' in these examples are referred to as syllabic. In English, these are typically nasals and liquids (i.e., /l, r/). Although it is uncommon, it has been claimed that some languages allow obstruents in the syllable nucleus, such as the Imdlawn Tashlhiyt dialect of Berber, which has words like *tFtKt* 'you suffered a sprain', where the fricative F and the stop K are syllabic (Dell & Elmedlaoui, 1985, p. 113; but cf. Coleman, 2001).

There are, however, a number of cases that remain problematic for a sonority-based definition of the syllable. A notorious example is the existence of word-initial sequences made up of a fricative followed by a stop, as in English *stone* or German *Stein* (/ftam/) 'stone'. According to the SSG, these words would consist of two syllables each, corresponding to the two peaks in sonority, that is, the initial fricative and the vowel. Similarly problematic cases are postvocalic sequences of a stop followed by a fricative as in *labs*, *width*, or *fists*, which also run counter to the SSG. Theories of syllabification have offered explanations based on the notion of extrasyllabicity, arguing that these segments are dependent on levels of prosodic structure that are higher than the syllable such as the foot, the prosodic word, or the prosodic phrase (Lieberman & Prince, 1977; Clements & Keyser, 1983; among others). More dramatic examples of clusters that violate sonority sequencing can be found in Slavic languages, as illustrated by the Russian word *мзда* (/mzda/) 'bribe' or the Polish words *bzdurny* (/bzɔrɲi/) 'silly' and *lwy* (/lvi/) 'lions'. Further, other challenges are posed by words like *cuddling* or *darkening* which would consist of two syllables following the SSG, but may be pronounced as three syllables by many speakers, as *cudd-l-ing*.

Despite these exceptions, the syllable can be described as a unit made up of minimally a sonority peak and possible margins of lower sonority. The next issue to consider is whether elements within a syllable are arranged according to a specific structure.

Syllable-Internal Structure

Among different accounts of syllable-internal structure, perhaps the most frequently described is the division into onset, nucleus, and coda (but see also Kahn, 1976, and Clements & Keyser, 1983, for flat structures without sub-syllabic constituents, and the

4 SYLLABLES

Figure 3 Syllable-internal structure: (a) ternary branching, (b) right binary branching, (c) left binary branching

Figure 4 Syllable-internal structure: examples from English

moraic approach discussed below). The peak of the syllable occupies the nucleus, prenuclear elements constitute the onset, and postnuclear segments make up the coda. Figures 3a–c illustrate three possible arrangements (C stands for consonant and V for vowel). Figure 3a shows a nonhierarchical structure (e.g., Haugen, 1956), Figure 3b illustrates a binary branching organization where the nucleus and the coda together constitute the rime (or rhyme) (e.g., Fudge, 1969; Blevins, 1995), and Figure 3c depicts an alternative binary structure with the onset and the nucleus forming the body (e.g., McCarthy, 1979). The nucleus is the only obligatory element, as illustrated by one-syllable words like English *I* or *awe*. A syllable may be onsetless, as in *arch*, or lack a coda, like *law*. Several consonants may be found in the onset, as in *straw*, or in the coda, as in *elves*, or in both, as in *blank*. Syllables that end in a vowel are called open or free syllables, whereas syllables that end in a consonant are known as closed or checked. Figure 4 shows the structure of the English one-syllable words *bat* and *blank* in an onset–rime organization.

Evidence for syllable-internal structure is drawn from different sources. On the one hand, there is evidence from common speech errors. Slips of the tongue frequently involve the transposition of segments occupying the same syllabic position, such as the production of *philosophy* as *phisolophy*, where both the [l] and the [s] occupy an onset position. Spoonerisms are a kind of speech error in which the commutation generates proper words, as in *You hissed my mystery lectures* for *You missed my history lectures*, attributed to the Oxford scholar Rev. William Spooner (1844–1930). This example also shows that two syllable onsets have been interchanged. Support for the onset–rime division comes from controlled experimental techniques such as word learning games and syllable manipulation tasks (Treiman, 1986; Treiman & Danis, 1988; Kapatsinski, 2009; among others). For example, in a task that required blending two CVC words into one (e.g., the non-sense words *pob* and *gaf*), English speakers tended to associate the onset of the first word with the rime (VC) of the second word (i.e., *paf*) rather than associate the body (CV) of the first word with the coda of the second word (i.e., *pof*) (Treiman, 1986, p. 484). Similar results were obtained

with real words. Different patterns, however, have emerged for other languages. Yoon and Derwing (2001) provide evidence from a series of experiments that the body-coda approach best captures the structure of the syllable in Korean.

Further evidence for the rime comes from languages in which the distribution of stress (i.e., prominence) or tone (type of pitch melody) in a word or phrase is influenced by the amount of structure in the syllables, that is, the syllable weight. In such languages there is a distinction between light syllables, which typically end in a short vowel (or a vowel and a consonant in some languages), and heavy syllables with a more complex rime consisting of a long vowel, or one or more consonants, or both. Crucially, it is generally the rime, and not the onset, that contributes to syllable weight. For example, in languages like Latin, stress falls on the penultimate syllable (the one before last), as in *refectus* 'set over', except when the penultimate syllable is light, in which case the preceding syllable carries stress, as in *existimo* 'esteem' (Kenstowicz, 1994, p. 292). The rime is precisely the part of the syllable involved in poetic rhyming patterns. For instance, lines in a verse are said to rhyme when they share all the sounds from the last stressed syllable on. Hence, words like *bite*, *fight*, and *write*, which share the same nucleus and coda, constitute a perfect rime, but the same effect is not obtained with *bite*, *bait*, and *boat*, which share the same onset and coda, or with *bite*, *mate*, and *goat*, which share the coda only.

The greater importance of the rime vis-à-vis the onset in many languages is one motivation for moraic approaches to syllable-internal structure in which morae, or units of weight, are assigned to elements in the nucleus and the coda, and syllable weight is determined by the number of morae (e.g., Hyman, 1985; Hayes, 1989; among others). This approach finds support in the existence of moraic writing systems like Japanese Hiragana and Katakana scripts (Rogers, 2005, p. 276), where characters correspond to morae rather than to segments or syllables.

In addition, the syllable, or syllable constituents, are also the domain of some segmental level processes. For example, the distribution of the variants or allophones of a given phoneme are sometimes best captured in terms of syllabic structure. English has a velarized variant of the sound *l* ([ɫ]), that is, produced with the back of the tongue raised toward the hard palate in addition to the alveolar constriction. In some English varieties velarized *l* occurs at the end of the word (e.g., *sill*) or before a consonant in word-medial position (e.g., *sil*ver), or before a consonant in word-final position (e.g., *sil*k). Referring to the syllable coda as the context for this pronunciation of *l* accounts for all three positions.

If syllables are to have internal structure, an issue to consider is how strings of sounds are organized into syllables. One prevalent principle is the fact that onsets tend to be maximized, that is, an intervocalic consonant is syllabified with the following vowel rather than with the preceding one. Similarly, a sequence of two intervocalic consonants will be syllabified with the following vowel so long as the sequence conforms to the sonority principle and is a permissible onset in that language. For instance, while *replace* can be syllabified as *re-plate*, a word like *dictate* would not be parsed as *di-tate* but rather as *dic-tate*, since *ct-* ([kt-]) is not a possible onset in English. In a number of cases, however, syllabification is not straightforward. Onset maximization predicts that words such as *lemon* and *panic* will be syllabified as *le-mon* and *pa-nic*. However, lax vowels like the 'e' in *lemon* and the 'a' in *panic* are restricted to closed syllables in English, and thus would require the words *lemon* and *panic* to be syllabified as *lem-on* and *pan-ic*. Speech error data and syllable manipulation experiments lend support to this division, although, in addition to the quality of the preceding vowel, other factors also influence the syllabification of the medial consonant, such as the position of stress, the type of consonant, and the spelling (Treiman & Danis, 1988; Derwing, 1992; among others). Such cases have led some scholars to propose that consonants can be ambisyllabic, that is, can belong simultaneously to the coda and the onset (e.g., Pulgram, 1970; Kahn, 1976).

Syllable Types and Phonotactics

Languages vary as to the shape of syllables they allow. The most common syllable is CV. While the nucleus is a necessary position in all languages, the number of elements that are required or allowed in other positions varies from language to language. Some languages, such as Arabic or Dakota, do not have onsetless syllables. Other languages lack codas, like Hawaiian or Fijian, or have strong restrictions on coda consonants, like Japanese, which only allows a nasal or part of a word-internal geminate (or double consonant) in the coda (see Blevins, 1995, for a typology and examples). If a language has syllables with complex onsets or codas (CCV, CVCC), it also has syllables with single onsets or single codas (CV, CVC). In English there can be up to three consonants in the onset, the first consonant in a sequence of three being the fricative /s/ alluded to above. English coda clusters can contain up to four segments, as in *sixths* (/sɪksθs/), *glimpsed* (/ɡlɪmpst/), *twelfths* (/twelfθs/), although in actual connected speech the cluster is likely to be simplified. Such long sequences of consonants typically end in a consonant with a coronal place of articulation (dento-alveolar region) such as /s, z, t, d/.

The knowledge about the number and possible combinations of segments that can be found in the different syllabic positions in a given language is called phonotactics. In English, for instance, /ŋ/ (the final nasal sound in *ring*) is found only in the coda, while /h/ is never found there. Sequences of more than one consonant in the onset or the coda tend to obey the sonority sequencing principle discussed above. Thus, in English we find onset clusters of increasing sonority made up of obstruents + sonorants, such as /br-/ and /tw-/ , as in *bread* and *twice*. Similarly, we find coda clusters of decreasing sonority such as /-lj/ and /-ft/ in *Welsh* and *draft*, and we also find sequences of equal sonority codas such as /-vz/ and /-pt/ as in *lives* and *apt*, again typically with a coronal consonant in final position.

Just as languages differ in the syllable types they allow, so they also differ in their phonotactics. Unlike English, Swahili and Cantonese allow /ŋ/ in onset position. In present-day English, a nasal can be followed by an obstruent in the coda, as in *lamp* or *ink*, but the reverse cluster, an obstruent (other than /s/) followed by a nasal, such as *kn-*, is not a possible onset (clearly, the *k* in *know* or *knee* is not pronounced). By contrast, Czech and German do allow such sequences, as in Czech *pnutí* 'tension' or German *Kneipe* 'bar'.

A language's phonotactic restrictions determine the extent to which foreign words will be modified when introduced in the language. For example, although Spanish has complex onsets, it does not have onsets consisting of an /s/ plus another consonant. As a result, a word like English *snob* is converted to a phonotactically acceptable form such as *esnob*, syllabified as *es-nob*. More dramatic adaptations can be observed in borrowings from English into languages with more limited syllable inventories, such as the Hawaiian word for *elephant*, [ʔelepani], or the Japanese word for club, [kurabu]. In these cases, in addition to some segmental changes, the English words have been modified by means of the insertion or deletion of segments so as to match the preferred CV syllable structure of the target language.

As we have seen, the syllable is a unit of phonology that contributes to different phonological phenomena such as stress assignment and allophonic distribution of sounds. Speakers have intuitions about the syllable, and the phonotactic knowledge of how sounds combine to form syllables and words in a given language is an integral part of what speakers know about their language. Despite the fact that its reality as a necessary phonological constituent is sometimes questioned, the syllable is a useful tool in descriptive and contrastive analyses of languages and is arguably the domain that best captures some linguistic generalizations.

Syllabus Design

PETER ROBINSON

Syllabus design involves decisions about the *units* of classroom instruction and organization, and the *order* in which they are to be taught, or organized for learners. These decisions are constrained, in different ways, by two *purposes* that syllabi fulfill in educational settings—to promote “learning” and to ensure “accountability.” With the first of these purposes in mind, choice of the unit of analysis for sequencing whatever is to be worked on in classrooms must draw on what is known of the psycholinguistic processes implicated in second language acquisition (SLA). Consequently, there are variations between proposals for syllabus design which reflect different theoretical positions on the psycholinguistically valid units of analysis for L2 learning, and also the sequence in which they should be presented to learners. One could call these “bottom-up” proposals, made by SLA researchers who are concerned with the *complementarity* of decisions about units and sequencing with what is known about *learning processes*, and the levels of L2 attainment that they lead to.

On the other hand, syllabi are necessary so that government agencies, institutions, and teachers can be *accountable* for what is taught in a program, and so that comparisons can be made across institutions, enabling instruction to be coordinated across settings and national boundaries (North, 2001). One could call these “top-down” proposals, which are concerned with the *feasibility* of implementing decisions about syllabus design across a range of settings and languages taught, and with how *comparable* their concomitant assessment procedures are with respect to the societal goals of L2 education. Since these “top-down” implementational considerations must logically assume the correctness of one or another of the “bottom-up” language-learning process proposals for syllabus design, only the latter are described in what follows.

Grammatical Syllabi

Since the 1920s, and the work of Harold Palmer and others in the Reform Movement who emphasized the controlled presentation of grammatical structures and oral practice following classroom presentation, grammatical syllabi have featured prominently in programs for second and foreign-language learners. Intuitive criteria of relative usefulness and simplicity were used as a basis of selection and grading, and these criteria continue to guide selection and sequencing of grammatical structures in many published teaching materials. Ellis (1997), however, provides a contemporary psycholinguistic rationale for adopting a structural, grammatical syllabus. He argues that explicit, declarative knowledge of L2 grammar can influence the development of implicit declarative knowledge, and through communicative activity implicit declarative knowledge can be proceduralized and used in spontaneous skilled performance. The main constraint on what structures should be taught, and when, is that learners must be developmentally ready to incorporate the explicit grammar instruction into their interlanguage. Ellis cites research by himself, Pienemann (1989), and others showing that learners pass through stages of development in the acquisition of, amongst other things, morphemes, question forms, and forms for expressing negation. Unless grammatical instruction is timed to the learner’s point of development, Ellis argues, it will not influence the developing implicit knowledge base.

2 SYLLABUS DESIGN

Since stages of development are learner-internal and hidden from the teacher, timing is difficult to manage. However, Ellis claims that explicit grammatical knowledge serves a number of other functions: it can be used to monitor production; it can help learners to notice features in the input; and it can help learners to compare their own production with a target model, and in some cases notice the gap between them. Knowing about grammar, Ellis argues, is therefore useful, and a structural syllabus can be used to organize and promote this knowledge.

Semantic Syllabi

In the 1970s the Council of Europe initiated a project (see Wilkins, 1976) which aimed to specify a common framework for teaching and assessing “communicative competence” in foreign-language education. The aim was to specify syllabi in terms of three categories of meaning common across languages; semantico-grammatical meaning or notions, such as “time” and “quantity;” modal meanings, such as degree of certainty and scale of commitment; and communicative functions, such as agreeing, requesting, or complimenting. These provided a way of going from specified types of meaning, or universal communicative and conceptual categories, to their token realization in specific languages. This is an unordered inventory: what provides sequencing constraints on these notional categories, and their realizations in language, is the idea of a common core of notions and functions, useful for all communicative goals and purposes, which must be mastered before those particular to specific communicative purposes. Similarly, Negueruela and Lantolf (2006) have recently proposed that concepts should be the minimal units of instruction, and that explicit instruction in grammar can “promote learners’ awareness and control over specific conceptual categories as they are linked to formal properties of language” (2006, p. 82). These conceptual units of instruction can be selected based on what is known of L2 development—for example, progressive aspect is first used in development to express the concept of activity and only later to express achievement—or they can be based on an analysis of the differences between how the languages already known and the language to be learned package concepts, such as time and motion, for grammatical expression.

Usage-Based Lexical Syllabi

The development of large-scale corpora over the last twenty years has also led to proposals for frequency-based syllabi which use lexical items or collocations as the units of syllabus design. For example, rather than structurally grading the grammatical content of the syllabus, Willis (1990) argued for grading it lexically using corpora of language use to identify word frequency at the 700-word, the 1,500-word, and the 2,500-word levels. Words in the corpora are itemized as collocations exemplifying each word’s typical patterns of use. In the lexical syllabus these three corpora are the bases of exposure at three levels of learner development. Willis claims that exposure is not sequenced or controlled within these levels, and the lexical syllabus “does not dictate what will be learned and in what order,” rather “it offers the learner experience of a tiny but balanced corpus from which it is possible to make generalizations about the language as a whole” (Willis, 1990, p. vii).

Task-Based Syllabi

Since the mid-1980s, tasks have been increasingly researched and theorized as a basis for syllabus design. In contrast to the units of syllabus design described above, tasks are a

nonlinguistic unit. Bygate and Samuda (2008), Long and Crookes (1993), and Skehan (2003) are in broad agreement about the psycholinguistic motivation for task-based syllabi, citing research showing (a) little resemblance between acquisitional sequences and instructional sequences based on linguistic forms (e.g., Lightbown, 1983); (b) evidence that learning is nonlinear and cumulative, rather than linear and additive as linguistic (structural, semantic or lexical) syllabi imply (e.g., Selinker & Lakshmanan, 1992); and (c) research showing the influence of learnability on the order in which items can be learned. In one proposal for task-based syllabus design (Long & Crookes, 1993) units of real-world activity involving language use identified on the basis of a needs analysis (target tasks) are subsequently broken down into simpler versions, which are presented in an order of increasing complexity, so as to eventually approximate the full complexity of the target-task demands. In this view, the nonlinguistic features of tasks contributing to their relative complexity are the basis of sequencing decisions. Robinson (2007) has described a taxonomy of task characteristics, and principles for sequencing increasingly complex pedagogic tasks based on it. In his SSARC model for task-based syllabus design (Robinson, 2010), the complexity of the *performative demands* that tasks make are increased across sequences of pedagogic task versions of target tasks (e.g., first performing the task with, and then without, planning time). Subsequently, the *conceptual demands* made by target tasks are increased across pedagogic versions (e.g., from “no causal reasoning” to “causal reasoning” demands). The rationale for this model is to first promote faster access to and *control* over what learners already know of the L2, and then to promote reanalysis and *development* of form–concept mappings that may need to be made in order to achieve success in target-task performance. Similarly, Duran and Ramaut (2006) describe a “complexity scale” which they developed to grade and sequence the “cognitive and communicative processing demands” of tasks for learners at basic and more advanced proficiency levels. In contrast, other proposals for task-based syllabi involve sequencing tasks according to specific linguistic criteria, so as to promote awareness of grammatical structures or lexical items provided in the input to task performance (Nunan, 2004). In these cases, pedagogic tasks are used to implement a linguistic syllabus, and so are more properly called language-based syllabi, with task practice activities.

Synthetic Immersive Environments and Second Language Pragmatic Development

JULIE M. SYKES

Synthetic immersive environments (SIEs) are engineered, digital spaces which draw on the complex, goal-directed, collaborative game-play behavior of massively multiplayer online games (MMOGs) “to produce explicit, educationally related outcomes in simulated, relevant interactional contexts” (Sykes, 2008, pp. 10–11). They represent a significant advance in pedagogical innovation, which allows for treatment of the complexities associated with a variable pragmatic system while, at the same time, teaching salient norms and patterns that may be especially useful for learners. In doing so, SIE creation and implementation has the potential to break down instructional barriers that second language (L2) pragmatics researchers have often linked to the lack of pragmatic instruction in the foreign-language classroom (e.g., Bardovi-Harlig, 2001; LoCastro, 2003; Rose, 2005; Félix-Brasdefer, 2007). Pragmatic competence requires the mastery of numerous different skills (e.g., recognition, comprehension, and production), as well as exposure to a variety of tasks and interactions allowing pragmatic behaviors to be developed and nurtured (Koike, 1994; Bardovi-Harlig, 2001; Kasper & Rose, 2002; LoCastro, 2003; Cohen, 2005). This entry gives an overview of the features of SIEs most relevant for L2 pragmatic development, presents a sample project, and suggests a possible research trajectory for continued work in this emerging area.

Significant Features of SIEs for L2 Pragmatics

Identifying significant features of SIEs for L2 pragmatic development requires an understanding of the principles of commercial game design work, games studies, and educational gaming. The ways in which features become meaningful in any immersive space will always remain specific to the players involved, the context of the digital environment, the design of the immersive experience, and, in the case of SIEs, the pedagogical objective of game play. Therefore, considering the characteristics of any immersive space and game-play experience is essential. Nevertheless, it is possible to target general elements that deserve special attention when considering language learning, and, more specifically, L2 pragmatics.

In a general overview, Purushotma, Thorne, and Wheatley (2008) present 10 key principles for video game design for foreign-language learning. These can be summarized as follows:

1. The key focus should remain on fail states.
2. The learning focus should remain primarily on meaning, with secondary attention to form.
3. All elements should be playful.
4. Metalinguistic explanations should be included separately from core game play.
5. Learning should be organized around tasks.
6. Gradual scaffolding of new content should be used.
7. Assessment should examine both process and product.

2 SYNTHETIC IMMERSIVE ENVIRONMENTS AND L2 PRAGMATICS

8. Designers and instructors should consider a full range of gaming platforms.
9. Games should allow for individual game-play choices by learners.
10. Multiplayer games should provide players with meaningful and distinct roles.

While their focus remains on all kinds of digital games, this compilation of research is especially important for those designing, building, and evaluating their own SIEs related to a variety of language learning objectives. Sykes, Reinhardt, and Thorne (2010) further explore the above principles as related to second language acquisition (SLA) research and practice. These authors provide a detailed explanation of fail states, task-based learning, and player interaction. Drawing on each of these theoretical discussions as well as work specific to L2 pragmatics (i.e., Sykes, 2009, 2010; Sykes, Oskoz, & Thorne, 2008), it is possible to highlight the components that are especially relevant for L2 pragmatic development. This section focuses on three features which have the potential to be especially important in overcoming existing barriers to L2 pragmatic instruction: individualized learning experiences; meaningful interactive spaces; and multiple, complex fail states with meaningful feedback. Each should be carefully considered when designing or evaluating SIEs for L2 pragmatic development.

Individualized Learning Experiences

Subjectivity, defined by Ishihara (2006) as “one’s view and perception of the world composed of individual dispositions (such as self-identity, values, beliefs, morals, feelings, and personal principles)” (p. 2), has been shown to have a profound impact on pragmatic choices in an L2 (Cohen, 1997; LoCastro, 1998, 2001). For example, research demonstrates that learners of Japanese and French consciously diverge from the pragmatic norms present in the target culture (e.g., the coding of hierarchy and gender), even if it means it might cause problems in future interactions (LoCastro, 1998; Saville-Troike, 1998; Ishihara, 2006). Creating experiences where individual learners are encouraged and empowered to make informed pragmatic choices is very difficult, yet essential.

In order to develop the strategies and skills needed to make informed pragmatic choices, learners must have the opportunity to experiment with, and understand, the impact of the various pragmatic choices they make. Moreover, they must have the opportunity to choose the contexts and scenarios most relevant to their interests and personalities, while at the same time engaging with meaningful content that may influence their pragmatic choices. SIEs can provide a learning space in which this can happen. They account for individualized experiences through character and game-play choices. For example, learners can choose the gender, personality, look, and movement of their avatar (i.e., their in-game character) as well as the number and types of quests (i.e., tasks or missions) they choose to complete. By encouraging learners to utilize the gaming environment for practice and learning in an individualized manner (e.g., selecting tasks and quests relevant to their own learning interests), it is predicted that students will become even better informed about the consequences of the pragmatic choices they make, an important step in L2 pragmatic development. Learners are able to experiment with different levels of adherence and establish a pragmatic system with which they are comfortable. Instructors are better able to evaluate the places in which gaps still occur as well as the crucial areas in which subjectivity plays a role in learner divergence through reflection and processing with the learners themselves.

Meaningful Interactive Spaces

Meaningful interactions are an important component of L2 pragmatic development. Learners need to be given choices over contexts, interactions, and perceptions (Kasper, 1997; Rose,

2005). While role-play scenarios and practice situations can be helpful, they are not necessarily sufficient for learners to internalize new pragmatic behaviors (Félix-Brasdefer, 2007). A key to successful pragmatic instruction is providing learners with meaningful interactive experiences, one of the reasons that conversation analysis and corpora analysis have become popular contexts for both research and instruction (see, for example, Belz & Vyatkina, 2005; González-Lloret, 2007, 2009).

SIEs also offer the possibility of providing meaningful, engaging interactional experiences, with both nonplayer characters (NPCs) and other interlocutors, quite different from those possible in a typical foreign-language classroom session (Thorne, 2003; Sykes, 2009). Learners not only participate in the interactions inherent in the SIE, but also have the opportunity to create their own contexts and control their own social environments. As a result, these types of immersive experiences add an additional level of pragmatic complexity and authenticity. This allows learners and instructors to simultaneously address the sociopragmatic features and pragmalinguistic formulas (Bardovi-Harlig, 2001; Félix-Brasdefer, 2002; Rose, 2005). Furthermore, through experimentation with a variety of sociopragmatic considerations, learners are given the opportunity to transform their interactional experiences in the L2 and further the development of their own pragmatic system.

Fail States and Feedback

Feedback represents one of the most difficult aspects of L2 pragmatic instruction. The instructor must determine whether a learner is making a pragmatic “error” based on lack of knowledge or understanding, or whether the deviation from the norm is intentional (Bardovi-Harlig, 2001). Therefore, scaffold feedback scenarios in which learners are able to feel the consequences of their choices (e.g., an upset interlocutor, a loss of an invitation, or an unsuccessful request) allow pragmatic feedback to move beyond a right/wrong approach to a more complex, realistic system. Through in-game monitoring and game play, instructors can also monitor progress and guide learners as needed to enhance the SIE learning experience.

Vital to the creation and implementation of this type of feedback system is the existence of fail states throughout the SIE experience. Fail states in SIEs can be explicitly designed to emulate genuine consequences of pragmatic miscommunication (e.g., gain/loss of invitations, heightened/lessened homesickness, more/fewer friendships), thereby encouraging multiple attempts at various tasks (i.e., practice) without significantly raising the affective filter. Purushotma et al. (2008) put forward the claim that “we should engineer the game to cater primarily to failure and partial success” because these fail states are vital to language learning. Since this feedback is inherent in the game, delivered through a variety of mechanisms (e.g., the loss/gain of assets, the ability to do certain things, additional help from the avatars in the space), learners are given permission to fail and experiment with language. This also serves as ongoing, leveled assessment of the learner’s L2 pragmatic abilities. Recreating an authentic experimentation and feedback experience in an immersive space affords learners the opportunity to test various types of pragmatic behavior prior to participating in interactions outside of the SIE. If learners gain the pragmatic skills necessary in the virtual space, they will be more prepared for interaction in other contexts as well. As is the case with any mediated environment, there is an inherent danger in learning the pragmatics of the environment itself, as opposed to L2 pragmatic skills that transfer to other interactional contexts. One must make careful design decisions when developing SIEs to enhance transferability. For further discussion see Sykes et al. (2008) and Thorne, Black, and Sykes (2009). Nevertheless, the benefits of providing meaningful, authentic feedback through varied fail states instantiate a strong need to create transferability.

Figure 1 Requesting a book from your host sister, Croquelandia © Julie Sykes

Sample SIE Project

Croquelandia was the first SIE explicitly designed to target L2 pragmatic abilities, specifically requests and apologies in Spanish. It is presented here not as an example of an ideal of what should be done, but rather as a real-world example of the possibilities for L2 pragmatic development via SIEs.

In Croquelandia, players set out on a series of missions (i.e., quests) in which they have to perform various types of requests and apologies. These fluctuate in difficulty based on differing levels of imposition, solidarity, and power; each scenario requires distinct types of pragmatic behavior. For example, in one scenario, a player loses a book and must ask to borrow it from his or her host sister, and in another, must apologize to a professor for missing an exam (see Figure 1). Successful completion of quests is based on the reaction of the character with whom the player is interacting and can be repeated for practice and experimentation purposes.

Tips and hidden clues are built in to the SIE, which includes the typical places encountered in study-abroad experiences: the host family's home, the plaza, the market, and the university. In addition to NPC interactions, players can interact with one another via synchronous voice and written chat in addition to an asynchronous discussion board.

Empirical research related to Croquelandia (Sykes, 2009, 2010) has been focused on the role that SIEs can play in enhancing advanced language learners' L2 pragmatic performance (i.e., their ability to perform requests and apologies in Spanish). Utilizing a synthesis of 120 hours of in-game behavior observation data, survey data, pre- and posttests, and one-on-one participant interviews, data were triangulated to gain a comprehensive picture of the impact of the SIE on pragmatic acquisition. This included the examination of in-game

behavior, user perceptions of their experience, and learning outcomes related to in-game participation. While many questions still remain, this project has pushed us one step further in determining when SIEs are especially useful (or not useful) in L2 pragmatic development.

Future Research in This Area

As this area of study advances in both depth and breadth, there are a number of important considerations related to SIEs and L2 pragmatic development which must be addressed. While empirical work has begun, additional research is imperative to understand how and when various types of digital games, and especially SIEs, may (or may not) be useful for L2 pragmatic development. Key questions related to further understanding of SIEs and L2 pragmatic development include the following:

- *Individualized experiences*: In what ways can we create meaningful individualized experiences for learners in SIEs? How is L2 pragmatic development influenced by tasks, learner choices, pragmatic content, and perceptions of these immersive experiences? Can similar (or better) experiences be created in commercially available digital games without the monetary and time investment required to develop an SIE?
- *Task design*: What types of tasks are best suited to L2 pragmatic development? How do these differ based on the areas of pragmatics being addressed as well as the type of SIE being created?
- *Interaction*: How can interaction with other players and NPCs be structured and enhanced to lead toward more productive L2 pragmatic development? What areas of L2 pragmatic development are best suited to interaction in immersive spaces? How does development through these interactions compare to other interactive experiences in both mediated and unmediated contexts?
- *Fail states and feedback*: How can fail states and feedback be incorporated to maximize L2 pragmatic development? How should fail states be structured to encourage experimentation for the enhancement of L2 pragmatic development? How can this feedback be used to enhance transferability of the skills learned in SIEs to other L2 contexts? What areas of L2 pragmatic development are best suited to this type of feedback?

This is not intentioned as a comprehensive list of all of the areas that still need systematic inquiry. Rather, it represents the wide variety of research projects to be undertaken as the field moves toward a more comprehensive understanding of the role SIEs can play in L2 pragmatic development. SIEs are by no means the only solution to overcoming barriers to L2 pragmatic development. However, initial research in this area reveals promising potential for continued advancements.

Systemic Functional Linguistic Approaches to Teaching English-Language Learners

MEG GEBHARD

This entry describes a sociocultural perspective on academic language development informed by Halliday's theory of systemic functional linguistics (SFL) (Halliday, 1996; New London Group, 1996). This perspective provides teachers with tools for supporting English language learners (ELLs) in recognizing the difference between everyday and academic language and in teaching students how academic language functions in the disciplinary texts students are routinely required to read and write in schools (Martin & Rose, 2003, 2008; Hyland, 2004; Schleppegrell, 2004; Christie & Derewianka, 2008). Therefore, from an SFL perspective, the job of the ELL teacher is to heighten students' awareness of the importance of linguistic variation and broaden students' abilities to use language more expertly and critically across a variety of social, academic, and political contexts (Gebhard, Demers, & Castillo-Rosenthal, 2008; Gebhard, Willett, Jiménez Caicedo, & Piedra, 2010).

Language and Education in SFL

SFL was first applied to primary and secondary education during the 1980s as a way of teaching academic literacies to linguistically and culturally diverse students in Sydney, Australia. Educational linguists, such as Christie, Derewianka, Kress, Macken-Horarik, Martin, and Rothery, drew on SFL to support teachers in making the workings of school-based language practices, or genres, transparent and potentially transformative for students, especially students from nondominant communities (Cope & Kalantzis, 1993). Despite important differences among SFL scholars, all share a sociocultural understanding of language and how academic literacies develop in schools that differs from behavioral and psycholinguistic orientations of language learning and teaching. An SFL perspective has three characteristics. First, academic language development is not understood in behavioral terms as a decontextualized process dependent upon students practicing a set of grammatical and rhetorical patterns. Nor do SFL scholars understand the ability of students to acquire academic language in purely psycholinguistic terms, which suggest humans have an innate capacity to develop language naturally in due course through oral interactions and engagement with texts. Rather, SFL scholars view language learning as a social process and language as a dynamic system of linguistic choices that students learn to use to accomplish a wide variety of social, academic, and political goals. From this perspective, teaching involves critically apprenticing ELLs to making more expert linguistic choices sensitive to the contexts in which they are interacting by exploring how language functions to construct relationships among participants (e.g., differences of familiarity and status), convey meaning or ideas (e.g., everyday versus disciplinary conceptions of events), and organize the flow of information depending on whether interactions take place orally, in writing, or through computer-mediated modes. These three functions, which Halliday calls interpersonal, ideational, and textual, operate simultaneously and offer teachers and students

2 SYSTEMIC FUNCTIONAL LINGUISTIC APPROACHES

a contextual basis for analyzing how language varies in relation to who is communicating with whom, what they are communicating about, and the modes through which they are interacting (Martin & Rose, 2003, 2008; Schleppegrell, 2004).

Second, SFL focuses on the range of linguistic choices available to culturally diverse students when they attempt to read and write academic genres such as narratives, descriptions, definitions, explanations, and arguments (Christie & Derewianka, 2008). From this perspective, the concept of linguistic choice operates simultaneously at the phonological, morphological, lexical, clause, rhetorical, and ideological levels, and reflects the degree to which students have been socialized into and wish to align themselves with valued ways of knowing and being at home, work, and school. As many studies have shown, schooled ways of using language, knowing, and being differ from everyday home and peer practices in significant ways (Heath, 1983). Based on their research with ELLs in the United States, Gebhard and her colleagues remark that these differences take on even more significance as students are required to read and write about unfamiliar topics using technical language and drawing upon meaning-making resources that differ greatly from the language practices students use at home or with peers. As such, these researchers maintain that "one of the goals of SFL-based pedagogy is to make visible and explicit the workings of academic English and support students in becoming critically aware of the differences between everyday and disciplinary language practices" (Gebhard, Harman, & Seger, 2007, p. 422).

Third, language variation is viewed as a political meaning-making resource that students can learn to use to position and reposition themselves in a rapidly changing world. As Luke (2000) makes clear, the work of the ELL teacher therefore is double-edged in that it:

is principally about building access to literate practices and discourse resources, about setting the enabling pedagogic conditions for students to use their existing and new discourse resources for exchange in the social fields where texts and discourses matter. These constitute the social semiotic "toolkit" that one puts to work in educational, occupational, and civic life. . . . Literacy education, then, is about access and inclusion, and potentially discrimination and exclusion. It is about setting the conditions for students to engage in textual relationships of power. (p. 449)

As described by the New London Group (1996), educators can do this kind of double-edged teaching by supporting students in critically analyzing and appropriating academic language to accomplish social, academic, and political tasks of relevance to them and their communities. They describe how teachers and students can accomplish this work through: (a) situated practice in using academic genres; (b) overt instruction in how to systematically analyze the linguistic features of genres and to develop a metalanguage for talking about how specific texts are constructed or "designed"; (c) critical framing to support students in standing back from what they are studying and viewing it critically in relation to its context; and (d) transformed practice, which puts academic language to work in other contexts (New London Group, 1996, p. 88). Using this approach, the goal of critical SFL pedagogy is not to canonize and reproduce academic language practices or to replace home and peer ways of using language. Rather, critical SFL works to acknowledge and value the multiple social and linguistic worlds to which students already belong and to support them in participating in and creating possible future worlds by expanding the meaning-making resources available to them.

SFL-Based Pedagogies

SFL pedagogies have been used internationally for many years (Cope & Kalantzis, 1993; Hyland, 2004; Whittaker, McCabe, & O'Donnell, 2009). The most widely known teaching

practice is the “curriculum cycle,” developed in the 1980s by educational linguists in Australia (Macken-Horarik, 2002). This approach has three phases. Phase one is a planning phase. From an analysis of a disciplinary genre students are routinely asked to interpret and produce in school, teachers design a project that will teach ELLs new disciplinary knowledge and associated language practices simultaneously over the course of the instructional cycle. Phase two is the modeling phase. Teachers explicitly guide students in critically analyzing representative text types to provide ELLs with access to both content and genre knowledge. This involves discussion about how the author has structured his or her text to achieve a purpose in communicating to an audience and how the author has used key words, phrases, and grammatical constructions to convey the content of the text, or “field,” to construct the intended voice, or “tenor,” and to support the flow of information, or “mode” (Martin & Rose, 2008, p. 19). Last, phase three is the production phase. With support from teachers and peers, students draft, revise, and edit their own texts, independently attending to how their linguistic choices construct the subject matter, maintain text coherence, and reflect their voices as members of various discourse communities. During this process, teachers provide ELLs with graphic organizers, guidelines for revision, and opportunities for collaboration and feedback.

SFL Pedagogy in the United States

In the United States, as in other countries, educational reforms over the last decade have placed increasing demands on ELLs and their teachers. As a result, a number of applied linguists have drawn on SFL scholarship to help teachers support the academic literacies of ELLs and speakers of nondominant varieties of English, particularly in the context of high-stakes school reforms such as No Child Left Behind legislation and English-only mandates (Achugar, Schleppegrell, & Oteiza, 2007; Brisk & Zisselsberger, 2010; Gebhard et al., 2010). In California, for example, Schleppegrell and her colleagues collaborated with teachers to analyze the academic language demands placed on students by state curricular frameworks and aligned exams (Schleppegrell, 2003). They identified the genres California teachers were required to teach and students were required to read and write in school (e.g., recounts, narratives, responses to literature, summaries, descriptions, explanations, reports, arguments, and analytic essays). In addition, they made recommendations regarding how state frameworks could be revised and aligned to support all students, not just ELLs, in developing “pathways” to academic literacy across disciplines as they transitioned from elementary to secondary schools (2003, p. 20). These pathways center on developing students’ (and teachers’) metalinguistics awareness of genre and register features as students progress from reading and writing more everyday texts such as personal narratives, descriptions, and procedures to reading and writing more technical and grammatically denser texts in specific content areas, including, for example, scientific laboratory reports, mathematical proofs, explanations of historical events, and analyses of literature.

With regard to history, Schleppegrell and her colleagues developed professional development institutes called the California History Project (CHP). These institutes introduced teachers to SFL tools they could use to deconstruct the meaning of textbook passages and primary source documents. Achugar et al. (2007) report that teachers planned lessons that enabled more in-depth discussion and understanding of history using these tools. In summarizing the findings of their study, these researchers report that students made significant gains on the California History–Social Science test (a standardized measure) and ELLs were among those who showed the greatest benefits (Achugar et al., 2007, p. 15).

In Massachusetts, Gebhard and her colleagues arrived at similar conclusions based on their work with elementary and middle school teachers (Gebhard et al., 2010). This project,

the ACCELA Alliance (Access to Critical Content and English Language Acquisition), provides sustained and reciprocal professional development to teachers, teacher educators, and literacy researchers by engaging in collaborative investigations of the academic literacy development of nondominant students attending urban schools. These case studies use SFL to assist teachers in designing curricular interventions based on the “Curriculum Cycle,” to support ELLs in negotiating the language demands of high-stakes exams and using academic genres to explore topics relevant to them and their communities. For example, second graders created a class blog to respond to each other’s writing (Shin, Gebhard, & Seger, 2010); fourth graders analyzed genre features in Puerto Rican children’s literature to write their own narratives (Gebhard et al., 2010); and fifth graders researched the benefits of recess to make an argument for reinstating recess in persuasive letters to their principal (Gebhard et al., 2007).

Similar to the finding of the California History Project, ACCELA case studies suggest that teachers developed a deeper understanding of both disciplinary content knowledge and associated language practices, both of which are essential components of teachers’ knowledge base. The data also reflect that ACCELA’s approach aided teachers in negotiating the imposition of scripted approaches to instruction and the language demands of high-stakes testing while making space for students to read and write about topics that mattered to them and their communities, and that SFL pedagogy supported emergent ELL writers in analyzing and producing more coherent and autonomous texts reflective of written as opposed to oral discourse.

Conclusion

In sum, research over the last three decades suggests that SFL pedagogies have the potential to support ELLs and their teachers in recognizing the difference between everyday and academic language and in teaching students how academic language functions in the disciplinary texts students are required to read and write across content areas. Moreover, recent studies conducted in the United States demonstrate that the use of SFL pedagogy can support teachers and ELLs in critically negotiating the demands of school reforms and to appropriate academic language to accomplish social action in and outside of school.

Systemic Functional Linguistics

JENNIFER HERRIMAN

Systemic functional linguistics (SFL; <http://www.isfla.org/Systemics/index.html>) was founded in the 1960s by M. A. K. Halliday, who developed the theory between the 1930s and 1950s from the work of J. R. Firth and his colleagues in London, among others (Halliday, 1967–8). In the 1970s, Halliday moved to Australia and the University of Sydney became the center of SFL. Since then the theory has spread and been applied to a large number of languages. Different versions of the theory have been developed by Fawcett (2000) (Cardiff grammar), Gregory (2002) (communication linguistics) and McGregor (1997) (semiotic grammar).

SFL starts from the premise that language is an instrument of social interaction which has evolved to meet our communicative needs in society (Halliday & Matthiessen, 1999; Bloor & Bloor, 2004). It does not exist as an autonomous formal system. Instead, it is a meaning-making resource which not only represents our world but actively constructs it. The form of language can therefore be best explained by examining it in relation to the functions which it has evolved to serve. The main focus in SFL is therefore on the analysis of authentic texts, that is speech and writing produced in real-life social interaction, rather than isolated sentences.

The language used in a text is determined by the context in which it is being used. There are two different types of context: the context of culture, or genre, and the context of situation, or “register” (Eggins, 1994, pp. 25–80). Genre is the institutionalized way that language is structured in various stages, in order to achieve a certain goal. A sales transaction, for instance, is normally achieved by a sequence of stages starting with a sales initiation and sales request, followed by a price and sales clarification, and completed by payment and purchase closure (Ventola, 1988). Register comprises three variables: *field*, *tenor*, and *mode*, each of which has an effect on how we use language. The *field* of a text is its content, that is what the language is being used to talk about, which may range from everyday topics to technical ones. The *tenor* of a text is determined by the social roles of the people involved in the communication and the relationships between them. This has three simultaneous dimensions: power, which ranges from equal to unequal relationships (e.g., close friends vs. employee and employer); contact, which ranges from frequent to occasional (e.g., spouses vs. acquaintances); and affective involvement, which ranges from high to low (e.g., lovers vs. business associates). The *mode* of a text is the way in which communication takes place, for example whether it is written, computer-mediated, spoken face to face or on the telephone, and so on.

These three variables are associated with three chief functions of language, which are referred to respectively as the *ideational*, *interpersonal*, and *textual* “metafunctions” (Halliday & Matthiessen, 2004, pp. 29–31). The field of a text is associated with the ideational metafunction. This is the usage of language to make sense of, and talk about, the world around us and within us. It has two components: the experiential and logical metafunctions. The experiential function is concerned with the content of language, and the way in which we represent our experience of the world as a kind of process, activity, state, or happening in which people and things are involved, and which take place in certain conditions (described in terms of who did what to whom and when, where, how, why, etc.). In, for

Table 1 Register and metafunctions

Field	Ideational	Experiential	Representing experience as a process with participants and circumstances
		Logical	Connecting representations of experience
Tenor	Interpersonal		Exchanging information or goods and services
Mode	Textual		Organizing the message

example, the statement *June reads the newspaper on the train*, experience consists of three component parts: the process of reading, two participants involved in this process (*June* and *the newspaper*), and one circumstance associated with this activity (its spatial location *on the train*). The logical function concerns the ways in which representations of experience may be connected to each other by different types of relationships, such as by simple addition, for example *June read the newspaper and Pete made the dinner*, or by a relation of dependency for instance a temporal relationship, such as *June read the newspaper while Pete made the dinner*.

The tenor of a text is associated with the interpersonal metafunction. This is the usage of language to establish and maintain relations with other people. This involves taking on different kinds of speech roles in communication. There are two main types: speech roles which exchange information (e.g., statements or questions) and speech roles which exchange commodities and services (e.g., offers or commands). Tenor also involves adjusting one's claims about the validity of what one is saying, for example by using *probably* in *She probably reads the newspaper on the train*, and expressing various kinds of attitudes, for example by using *fortunately* in *Fortunately, he makes the dinner every Sunday*.

The mode of a text, finally, is associated with the textual metafunction. This is the usage of language to organize these ideational and interpersonal meanings into a coherent message which fits in with the other messages surrounding them and with the wider context in which talking or writing takes place. This metafunction is therefore referred to as the "enabling" function (Halliday & Matthiessen, 2004, p. 30). The relationship between register and metafunctions is represented in Table 1.

Language creates these three kinds of meaning—ideational, interpersonal, and textual—simultaneously. Each clause, then, represents a part of human experience, that is, some process, change, or state in the external or our own internal environment (ideational meaning); it interacts with others in some way (interpersonal meaning); and it is organized as a message which fits in with the language around it (textual meaning). The way in which we create these different kinds of meanings is a process of choosing from finite sets of choices, or "system networks," in the language system (Egins, 1994, pp. 198–219). Choices are made on three levels: the level of meaning itself ("discourse semantics"), the wordings which realize these meanings (i.e., syntax, lexicon, and morphology, which together make up "the lexicogrammar" of a language), and the sounds or letters used to express them (phonology or graphology). These choices are not made consciously, but depend on the context in which the language is used. They become meaningful because there is an opposition between what is chosen and what is not.

Each of the metafunctions of language has its own system networks. The chief system in the ideational metafunction is the system of "transitivity" (Halliday & Matthiessen, 2004, pp. 168–305). (This term is used here in a broader sense than its traditional meaning of whether verbs take objects or not.) This is the choice of what kind of process takes place, who or what participates in this process, and what kinds of circumstances may be associated with any of these processes, such as conditions of time, place, and manner, and other

Table 2 Processes and participants

<i>Process type</i>	<i>Example</i>
Material	<i>Tim (actor) made (process) a copy (goal) for Rose (beneficiary).</i>
Mental	<i>Pete (senser) didn't know (process) the correct answer (phenomenon).</i>
Relational	<i>This river (carrier) is (process) dangerous (attribute).</i> <i>That tall man over there (value) is (process) my brother (token).</i>
Verbal	<i>We (sayer) told (process) her (receiver) the exciting news (verbiage).</i>
Behavioral	<i>John (behavior) coughed (process).</i>
Existential	<i>There is (process) a better solution (existent).</i>

constraints such as cause, reason, and concession. There are six types of processes, and each process type has its own set of participant roles. Material processes are processes of doing and happening, such as *make*, *throw*, *go*, *give*, and *perform*. They always have an actor who is carrying out the doing or happening, and they may also occur with other participants, such as the goal, which is the person or thing to which the activity is done, or the beneficiary, which is the person or thing that the activity is done for. Mental processes are processes of thinking, seeing, or feeling such as *believe*, *know*, *hear*, *realize*, *like*, *hate*, and so on. The chief participants are the senser, which is typically a human being, and the phenomenon, which is what is sensed. Relational processes are processes of being and having, such as *be*, *seem*, *look*, *appear*, *have*, *own*, and so on. They may be descriptive, with a carrier and its attribute, or identifying, with a token and its value. Verbal processes are processes of saying, such as *tell*, *ask*, *complain*, *order*, and so on; the chief participants are the sayer, the receiver, and the verbiage, what is said. Behavioral processes are processes of human physiological and psychological behavior, such as *cough*, *smile*, *dream*, *cry*, and so on; and finally, existential processes are processes of existing, such as *be*, *exist*, *remain*, *follow*, *occur*, and so on. These have only one participant, the behavior, and the existent. Together these six process types make up the outer world of physical experience, the inner world of consciousness, and the world of abstract relations (see Table 2). They are not discrete categories, but shade into one another, forming a model of experience which can be visualized as a circle (Halliday & Matthiessen, 2004, p. 172) (see Figure 1).

In addition to the transitivity system, which perceives the world in terms of whether an activity has an impact on another participant or not, there is another system for encoding our experience of the world: the system of ergativity (Davidse, 1992; Halliday & Matthiessen, 2004, pp. 280–302). This is when experience is presented from the perspective of whether a process happens by itself, for example *The vase broke*, or whether it has been caused by external factors, for example *Paul broke the vase*.

The interpersonal metafunction has network systems for interaction with others: the systems of mood, and modality. Mood is the choice of declarative, interrogative, or imperative clause types in order to carry out different speech roles (Halliday & Matthiessen,

Table 3 Modality

Likelihood	<i>It might happen.</i>
Inclination	<i>I want it to happen.</i>
Usuality	<i>It usually happens.</i>
Obligation	<i>It must happen.</i>

Figure 1 Process types in English (a simplified model of experience)

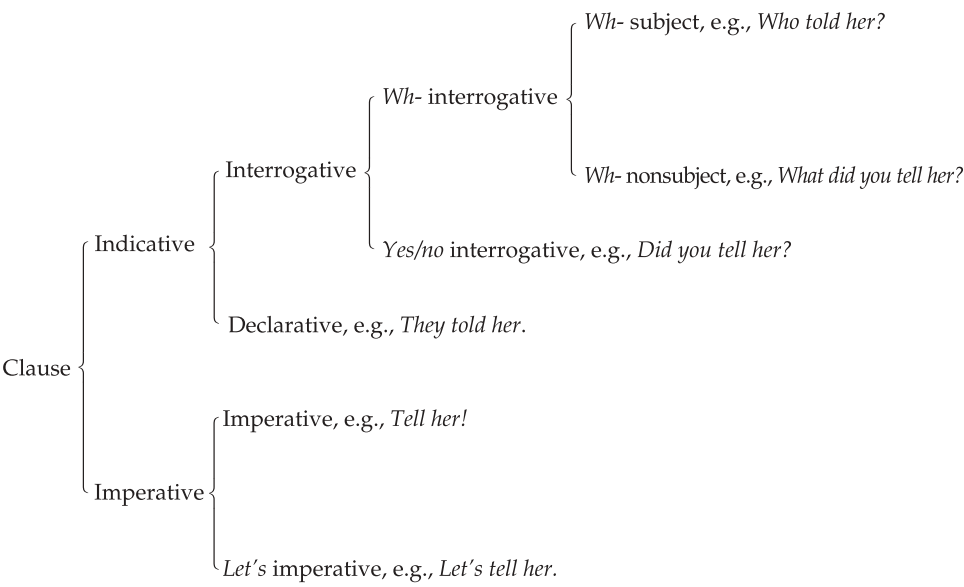

Figure 2 A simplified system network for mood in English

Table 4 Appraisal

Engagement	Monoglossic	<i>Ken has resigned.</i>
	Heteroglossic	<i>Peter said/It is said that Ken has resigned.</i> <i>Ken may/must have resigned.</i>
Attitude	Affect	<i>I am happy/disappointed about this.</i>
	Judgment	<i>He's a dishonest/reliable/capable person.</i>
	Appreciation	<i>This is a beautiful ring.</i>
Graduation	Force	<i>This is very/slightly dangerous.</i>
	Focus	<i>He's no/a real gentleman.</i>

2004, pp. 134–43) (see Figure 2). Modality is the expression of judgments of likelihood, inclination, usuality, or obligation (Halliday & Matthiessen, 2004, pp. 146–50) (see Table 3).

The interpersonal function also involves choosing who or what is to be made modally responsible for the activity that takes place. This is done by making it the subject of the finite verb in the clause (Halliday & Matthiessen, 2004, pp. 117–20). (In, for example, *John/the stone broke the window* and *The window had been broken*, modal responsibility for the activity of “breaking” is assigned to the subjects, *John*, *the stone*, and *the window*, respectively.)

The interpersonal metafunction has a network system for evaluative meanings, the appraisal system (Martin & White, 2005) (see Table 4). This is made up of three subsystems: engagement, attitude, and graduation. Engagement is concerned with the extent to which speakers engage with alternative voices in their texts, that is whether they choose to ignore them altogether by issuing categorical statements (monoglossic), or whether they choose to acknowledge their existence (heteroglossic, i.e., dialogism in a Bakhtinian sense). The latter may be done explicitly by attributing what is being said to another source, or implicitly by, for instance, qualifying what is being said with expressions of doubt, certainty, and so on. Attitude is made up of affect (feelings, such as happiness or disappointment), judgment (the evaluation of someone’s character and behavior), and appreciation (the evaluation of things). Graduation, finally, is concerned with up- or downgrading the force and focus of what is being said.

The textual metafunction has three main network systems for organizing the content of the message into a text: the systems of information (Halliday & Matthiessen, 2004, pp. 87–92), cohesion (Halliday & Hasan, 1976; Halliday & Matthiessen, 2004, pp. 524–85), and theme and rheme (Fries, 1995; Halliday & Matthiessen, 2004, pp. 64–87 and 93–105). Cohesion is the way in which speakers connect meanings to each other both within and across sentences, for instance by using pronouns to refer back to something mentioned earlier, or using conjunctions which connect the message in different ways. The information system is the way speakers organize language into units of given and new information, depending on what they wish to present as already known or unknown to their addressees. This is usually signalled by intonation. The system of theme and rheme, finally, concerns the way in which speakers order the content of the message into its point of departure (the theme) and what is to follow on (the rheme). What is typically selected as the theme depends on the type of clause. In English declarative clauses, the theme is typically the subject; in *wh*-interrogatives, it is the *wh*-element, the missing piece of information that is being asked for, and in imperatives it is the verb (see Table 5).

Themes may be simple, in which case they consist of experiential meaning only, for example *the house*, or multiple, in which case they are preceded by textual or interpersonal meanings. Table 6 depicts a multiple theme which is maximally extended by both textual and interpersonal meanings (Halliday & Matthiessen, 2004, p. 81).

Table 5 Themes and rhemes

Clause type	Theme	Rheme
Declarative	<i>The house</i>	<i>had been burgled the night before.</i>
Interrogative	<i>Who</i>	<i>burgled the house?</i>
Imperative	<i>Listen</i>	<i>carefully to what I am saying!</i>

Table 6 Multiple theme

	Theme		Rheme
Textual	Interpersonal	Experiential	
<i>Well, but then</i>	<i>surely Jean wouldn't</i>	<i>the best idea</i>	<i>be to join in.</i>

Speakers are able to give prominence to different parts of a text by rearranging the content into the theme and rheme. For instance, an unusual element may be made into the theme, such as the object, for example *These matters* (theme) *we'll deal with later* (rheme); one element may be singled out and placed in focus as the theme, for example *It was Ann* (theme) *who made the cake* (rheme), and the content of a message may be split into two parts in an identifying theme and rheme structure, such as *What Ann wants* (theme) *is another piece of cake* (rheme).

Choices from these network systems are made simultaneously on the different levels of language, that is, meanings are realized by wordings from the lexicogrammar, and these are expressed by letters or sounds. Most choices of meanings and their wordings are so usual that they are perceived as natural and straightforward. Processes and their participants, for instance, are typically realized in the lexicogrammar by verbs and nouns, respectively. Similarly, commands and questions are typically realized by imperative and interrogative clauses (direct speech acts). It is, however, possible to pair meanings with less typical wordings, thereby creating what is referred to within SFL as “grammatical metaphors” (Simon-Vandenberg, 2003; Halliday & Matthiessen, 2004, pp. 586–658). There are two chief types of grammatical metaphors: ideational and interpersonal metaphors. Ideational metaphors are less typical choices from the system of transitivity (Halliday & Matthiessen, 2004, pp. 635–58). This is when, for instance, instead of realizing a process and its participants by its natural wording as a clause, for example *The company developed the product*, these meanings are encapsulated in a noun phrase, for example *product development*. This results in a different representation of experience where the process and its participants have become a new entity that may, in turn, participate in another process, for example *Product development has caused us a lot of problems this year*, where *product development* is the subject of a material process and thereby represented as the actor responsible for causing *a lot of problems*. Using ideational metaphors such as these allows writers to pack more information into the clause. Ideational metaphors tend to emerge in late childhood, and are typical of academic writing (Halliday & Martin, 1993). Interpersonal metaphors are less typical choices from the systems of mood and modality (Halliday & Matthiessen, 2004, pp. 613–35). Metaphors of mood are indirect speech acts, when, for instance, a command is realized by an interrogative clause, for example *Could you pass the salt?* rather than by an imperative, or when a question is realized by a declarative clause, for example *I wonder where he's hidden the key* rather than by an interrogative. These metaphors are an

important negotiating resource in conversation, as they allow a speaker to attend to their addressee's positive or negative face. Metaphors of modality are when modal meanings such as likelihood are represented by separate clauses, for example *I think that he has arrived already*, or *It is likely that he has arrived already*, instead of within the clause by their more natural wording as modal verbs or adverbs, such as *may/might*, or *perhaps*. These metaphors are a means of making one's opinion explicitly subjective (e.g., *I think*) or explicitly objective (e.g., *It is likely*).

A text, then, is the outcome of the series of choices which makes up its meanings. As these choices are determined by the context in which language is being used, certain types of text are characterized by patterns of probabilities. Sports reports, for instance, are likely to have many material processes; recipes are likely to have more imperatives than, for instance, academic writing; and biographies are likely to have human participants and temporal expressions as their themes.

SFL has a strong commitment to usefulness, and has been applied to a wide range of areas. These include child language development (e.g., Painter, 2000) and educational linguistics (e.g., Schleppegrell, 2004; Christie, 2005), stylistics (e.g., Toolan, 1998), computational linguistics and artificial intelligence (e.g., Teich, 1999), and the study of language disorders, such as aphasia (e.g., Armstrong, Ferguson, Mortensen, & Togher, 2007). SFL is also frequently used for critical discourse analysis (e.g., Bloor & Bloor, 2007) and the analysis of multimodal texts (e.g., O'Halloran, 2006).

Tannen, Deborah

CYNTHIA GORDON

Introduction

Deborah Tannen, University Professor and Professor of Linguistics at Georgetown University (Washington, DC), is best known for elucidating the role of language in interpersonal relationships. A widely recognized public intellectual, Tannen is author of three books that spent time on the *New York Times* best-seller list, most notably *You Just Don't Understand* (1990), which examines gender differences in communication and spent nearly four years on the list (eight months as number one). Tannen is also an extremely accomplished scholar; she is a substantive contributor to topics as varied as language and gender, intercultural communication, linguistic strategies in spoken and written discourse, and family communication. In addition, Tannen has helped shape the subfield of discourse analysis into one that embraces its status as an applied variety of linguistics.

Biography

Deborah Tannen (born 1945) entered linguistics via literature and composition. She earned, in English literature, a BA at Harpur College (now subsumed under Binghamton University, SUNY) and an MA at Wayne State University (Detroit, MI). Tannen was teaching writing at Lehman College (CUNY) when she decided to attend the 1973 Linguistic Institute at the University of Michigan, which focused on “language in context,” a rather new subject in the (then Chomskyan grammar-dominated) field. Inspired by courses taken with A. L. Becker and Robin Tolmach Lakoff, Tannen pursued MA and PhD degrees in linguistics at the University of California, Berkeley. There she studied with Lakoff, John Gumperz, and Wallace Chafe. Tannen was appointed Assistant Professor at Georgetown University in 1979, completing her PhD the same year.

While Tannen is now associated with “discourse analysis”—a diverse, primarily qualitative set of approaches to studying conversation or language use—the term was not widely used when she was starting out. Tannen not only served (with Gumperz) as a pioneer in the discourse analytic approach of interactional sociolinguistics, but also sought to build connections with other approaches such as conversation analysis. She organized the 1981 meeting of the Georgetown University Round Table on languages and linguistics (GURT), bringing together scholars in the burgeoning area of discourse analysis and showing its broad applicability. She also organized the 1985 LSA/TESOL Institute (a joint institute of the Linguistic Society of America and Teachers of English to Speakers of Other Languages) on “Linguistics and Language in Context: The Interdependence of Theory, Data, and Application,” connecting to it a GURT conference addressing the same theme. GURT proceedings (Tannen, 1982a; Tannen & Alatis, 1986) include multiple participants who profoundly influenced the field, including Becker, Gumperz, Lakoff, Emanuel Schegloff, Frederick Erickson, William Labov, Ron Scollon, and Teun van Dijk.

Tannen’s seven general-audience books have brought linguistics to the public; these include best sellers *You’re Wearing THAT?* (2006), *You Were Always Mom’s Favorite!* (2009),

and *You Just Don't Understand* (1990). Tannen has appeared frequently on national television and radio, and writes regularly for major newspapers and magazines, including *the New York Times* and *Washington Post*. She is even more prolific within academia, authoring four books and editing or coediting eleven, and publishing over 100 articles, chapters, and essays. Tannen's research has appeared in major academic journals, among them *Language*, *Language in Society*, and *Text & Talk*. She also serves on the editorial boards of major journals.

Contributions

Tannen's diverse contributions are summarized in what follows.

Interactional Sociolinguistics as an Approach to Intercultural Communication

Tannen is most closely associated with interactional sociolinguistics, founded by Gumperz (1982), to explain the role of sociocultural knowledge in establishing involvement and conveying meaning in interaction. Much of Gumperz's work focused on how speakers of different cultural backgrounds use language and paralinguistics to indicate how they mean what they say. Tannen's focus on sub cultural differences extended Gumperz's approach. In her dissertation, Tannen analyzes an audiotaped, transcribed Thanksgiving dinner conversation of six friends, three of New York Jewish extraction (including Tannen) and three Gentiles (two from California, one from England). Published as *Conversational Style* (2005), the book serves as a primer in interactional sociolinguistics.

"Conversational style" refers to "the basic tools with which people communicate," including features of talk like pausing, pitch, and narratives (Tannen, 2005, p. 4). Tannen's book reveals how style similarities often produce positive exchanges, whereas even minor differences can cause consequential misunderstandings. For example, simultaneous talk—talking while another speaker is talking—was used and understood differently by different participants in Tannen's study. The New Yorkers tended to "talk along" with others to show interest; while appreciated amongst themselves, this strategy was interpreted negatively—as interruption—by those not sharing this style.

Also an innovation was Tannen's examination of motivations behind style differences. Building on linguistic politeness and communicative style research by Lakoff (e.g., 1975), Tannen demonstrates how language serves humans' simultaneous needs for connection and independence. She thus relates her argument to Brown and Levinson's (1987) discussion of politeness strategies and positive face (akin to connection) and negative face (akin to independence). Tannen devises a style continuum ranging from *high-involvement* to *high-considerateness*; while speakers of the former style (like the New Yorkers) focus on serving the other person's needs for solidarity, speakers of the latter (like the Californians) focus on honoring the other's independence. Neither style is "good" or "bad," although interaction between them is potentially problematic.

Conversational Style provides the theoretical backdrop for *That's Not What I Meant!* (Tannen, 1986), which demonstrates Tannen's commitment to raising awareness of how linguistics contributes to understanding interpersonal relationships.

Language and Gender

You Just Don't Understand (Tannen, 1990), which develops one chapter of *That's Not What I Meant!*, was a general-audience blockbuster. And, as Lakoff's (1975) *Language and Woman's Place* ignited linguistic research on gender in the 1970s, Tannen's book initiated the area's second explosion in the 1990s.

Tannen (1990) takes a cultural approach, building on Maltz and Borker's (1982) conceptualization of female-male communication as a kind of intercultural communication. She suggests that women and men tend to have different conversational rituals. Whereas all conversations balance connection and hierarchy, conversational rituals common among women tend to emphasize connection, while those common among men tend to focus on relative status. Like Maltz and Borker, Tannen traces these differences to research on children's socialization in same-sex playgroups.

As regional style differences can cause misunderstandings, so too can gender-related differences. For example, Tannen observes that many women engage in troubles talk to create interpersonal connection through symmetry, whereas many men create connection through competition-based rituals, like exchanging playful insults. When these differing patterns intersect—as when a man responds to a woman's complaint with advice, rather than a matching complaint—mutual frustration sometimes results. The book's observations and arguments had profound cultural effects; for instance, the now-ubiquitous observation that men generally don't like to ask for directions traces to *You Just Don't Understand*.

Tannen's academic publications have further investigated the complexity of gender and communication. Borrowing terminology from Goffman (1977), Tannen (1996) emphasizes that behaviors are "sex-class-linked": They are linked to the class of women (or men), and not necessarily to individuals. This highlights how speakers show their alignment with a given class moment-by-moment, and thereby construct their own gendered identities in interaction. Further, Tannen offers a nuanced understanding of how relational dimensions of particular interest to gender scholars are constantly being negotiated in all interactions. Importantly, she points out that a single strategy, like simultaneous talk, or being silent, could be a move either for power or solidarity (hence are ambiguous), or both at once (hence, polysemous).

Tannen's publications on gender provide a touchstone for many follow-up studies, both congenial and critical. With its focus on differences between gendered styles, her work is often contrasted with studies focused more explicitly on power (the "dominance" approach). Tannen's frustration with this tendency to reduce complex interrelated phenomena to a two-sided "argument" between scholars in opposing camps led her to write *The Argument Culture* (1998), in which she encourages multifaceted dialogue rather than dualistic debate in numerous realms, including academia.

Spoken and Written Discourse Strategies

Talking Voices (Tannen, 2007 [first published in 1989]) is Tannen's fullest account of how linguistic strategies create meaning in interaction. It demonstrates how "literary" strategies—specifically, repetition, dialogue, and imagery creating details—are the same strategies that make up everyday conversations. This book is the capstone of Tannen's work in the 1980s on orality and literacy (e.g., 1982b); it also brings that research into dialogue with her analyses of conversational discourse.

An important, broad function of the strategies *Talking Voices* examines is achieving "conversational involvement," or "an internal, even emotional connection individuals feel which binds them to other people as well as to places, things, activities, ideas, memories, and words" (Tannen, 2007, p. 27). "Constructed dialogue"—a term Tannen introduces as an alternative for the traditional term referring to quotation, "reported speech," is one involvement-creating strategy. She builds on theorizing by Bakhtin (1975/1981) and others to suggest that "reporting" previously uttered speech is impossible, because recontextualizing words (even if as word-for-word repetition) fundamentally alters their meaning. As Tannen (2007, p. 109) states, "the construction of dialogue represents an active, creative, transforming move."

This quotation evokes the recent burst of interest in linguistics in intertextuality, or textual interconnectedness. In fact, in the introduction to the second edition of *Talking Voices*, Tannen (2007) remarks that the book can be viewed as arguing for a theory of intertextuality that links repetition and recontextualization to meaning-making and relationship-building.

Framing and Family Relationships

Another theoretical concept to which Tannen has contributed greatly is Goffman's (1974) "frame," which refers to what is taking place at a given conversational moment, or the definition of the situation. Tannen's interest in framing began in her exploration of cognitive frames underlying oral and written narrative accounts (see Tannen, 1979). Contributions to Tannen's (1993) edited volume *Framing in Discourse* further develop framing by showing how frames are linguistically constructed, and how participants negotiate alignments within frames. The book also reveals the applicability of a framing approach to numerous contexts, from small-group discussions, to sermons, to medical encounters.

Framing continues to be of interest for Tannen, who, since 1999, has concentrated on family discourse. She codirected (with Shari Kendall) a study for which four American couples with at least one child audio-recorded their own conversations nearly non-stop for one week. This study further develops a linguistic understanding of framing while investigating how family members use language to create and negotiate identities, relationships, and beliefs (see Tannen, Kendall, & Gordon, 2007). Tannen develops additional aspects of her earlier work in analyzing these family conversations; for instance, Tannen (2004) identifies a special kind of constructed dialogue she calls "ventriloquizing," demonstrating how a speaker takes on the voice of a copresent pet or preverbal child as a resource for communicating with another family member.

Tannen (e.g., 2006, 2009) has also published general-audience books on family conversation, once again making the results of academic research in the field of linguistics available to the public.

Conclusion

Deborah Tannen has played an important role in developing discourse analysis, including shaping its key terms (like intertextuality and frame), methods (from collecting data to engaging in academic discourse), and topical interests (like spoken and written language, the discourse analysis of conversation, and language and gender). Her work has substantially advanced academic and lay understandings of human communication and relationships. In other words, Tannen is not only a discourse analyst but an extraordinarily productive contributor to applied linguistics (her Web site is: www.deborahannen.com).

Tarone, Elaine

BONNIE SWIERZBIN

The most succinct summary of the applied linguistics and teaching career of Elaine Tarone (1945–) is the title of one of her early books: *Focus on the Language Learner* (Tarone & Yule, 1989). Her research and teaching career has focused on second language (L2) learners as social beings in a variety of contexts and has emphasized the effects of those contexts on both the learners' use of language and the manners in which they learn it. She is one of the leading theorists of variationist second language acquisition (SLA), which has as its fundamental premise that the form of second language learners' utterances can vary dramatically depending on the learners' perceptions of social contextual variables such as the interlocutor, task, or topic. In a variationist perspective of SLA, variability in a learner's interlanguage (IL) (e.g., *I study grammars* vs. *I study grammar*) is not viewed as "noise" in the researcher's data or necessarily as errors for a teacher to correct; instead, variability is considered to be a potential source of new language forms appearing in the learner's IL and an indicator of transition in the language development process.

Variationist approaches to SLA draw upon the theory and methodology of the sociolinguistics of language. As described in Bayley and Tarone (in press), variationist SLA includes five central theoretical assumptions. The first is that just as every first language speaker has a range of speech styles for use in a variety of social circumstances, an L2 speaker has a range of interlanguage styles which depend on the social context. For L2 speakers as for first language speakers, styles range from informal (vernacular) to formal. The second assumption is that, of these styles, the learner's vernacular style, used in meaning-focused communication, is the most systematic. This means that learners' interlanguage may be more fluent and accurate in some contexts than in others, so that a researcher investigating or a teacher evaluating a learner's IL in just one context is not seeing an accurate or complete picture. In addition, although a learner's IL is systematic, it follows the learner's own rules; that is, each learner may have a different view of what the target language rules are, which is the third theoretical assumption. The next central assumption is that the speech of an L2 learner is impacted by the identity of the researcher just as it would be by any interlocutor. In particular, a learner may be influenced by the presence of a researcher to produce a more formal style rather than the vernacular the researcher wishes to observe. The final assumption is related to the sociolinguistic notion of a speech community, that is, speakers grouped into a common social category, for example, a neighborhood, academic discipline, or religious affiliation, and who share linguistic norms. Although this notion is extremely useful for the study of linguistic variation in traditional sociolinguistics, the assumption in variationist SLA is that the relevant speech communities for L2 learners are difficult to identify and that these learners may not construct their identities in a way that is consistent with the categories that are prevalent in traditional sociolinguistics, resulting in individual patterns of L2 language acquisition that vary from the patterns found in groups to which the learner may belong.

These assumptions have been empirically tested in studies by Tarone and others working with the variationist paradigm using methodologies that borrow from the Labovian framework of sociolinguistics. Several methodological characteristics are typical of this framework. First, studies examine both longitudinal and cross-sectional data. Next, they employ multiple elicitation tasks that are designed to demand differing amounts of attention

to speech. Finally, the tasks elicit data on multiple linguistic levels including phonological, morphological, and syntactic (Tarone, 1988). Studies producing evidence that the use of learner language is affected by social context include Tarone and Parrish (1988), Major (1999), Geeslin (2003), and Mougeon, Rehner, and Nadasdi (2004). One particularly important study linking this work to interlanguage development is Tarone and Liu (1995), which provides a longitudinal account of a 5-year-old Chinese boy learning L2 English (also described in Liu, 2000). The child was observed in three social contexts: playing with researcher Liu, who was a family friend, working at his school desk with peers, and interacting with his teacher. The play context was the one in which each new stage of English questions tended to emerge, spreading next to the peer context. New stages always occurred last in interactions with the teacher. The play context also appears to have stimulated a change to the supposed universal order of acquisition of English questions, with Stages 4 and 5 appearing there weeks before Stage 3 questions emerged in peer interactions. Thus, social context affected the stages of second language development in one of the only longitudinal studies to have tracked these two variables.

Born in Modesto, California, Elaine Tarone received a BA in English and Spanish from the University of California at Berkeley (1966) along with a lifetime secondary teaching credential, also in English and Spanish (1967). In 1969 she was awarded a diploma in Applied Linguistics from Edinburgh University, Scotland, where department chair S. P. Corder and Fulbright scholar Larry Selinker were challenging behaviorist views of second language development. The following year she earned an MA and in 1972 a PhD, both in Speech Science from the University of Washington, Seattle, where she wrote her dissertation while riding on the ferries plying Puget Sound. Her early work included a study on intonation in African American Vernacular English (AAVE), heavily influenced by sociolinguist William Labov's pioneering work with urban dialects (Labov, 1966, 1972). Her dissertation on intonation patterns in AAVE was the first on this topic.

At both Edinburgh University and the University of Washington, Tarone's perspective and intellectual development were deeply influenced by and, in turn, influenced the ideas of Larry Selinker while interlanguage theory (Selinker, 1972), the first major effort to explain L2 acquisition, emerged amid his discussions with students and colleagues. As the interlanguage hypotheses were being developed, Tarone introduced sociolinguistic theory in order to explain the variation that Selinker found in IL data, and variationist SLA, Tarone's interpretation of interlanguage theory, was born.

As a graduate student at the University of Washington, she was part of the "Washington school" of rhetorically based research on English for science and technology (EST) led by Louis Trimble. In analyzing scientific and technical writing under the guidance of Trimble and Larry Selinker as they taught specialized English as a second language (ESL) courses for engineering students, the research group members learned how to ascertain the major characteristics of particular English registers, and, just as importantly, how to supply a framework for ESL students to employ as they in turn analyzed texts in their specific scientific domains. Working with Trimble profoundly influenced Tarone's research (e.g., Tarone, Dwyer, Gillette, & Icke, 1981). In addition, his pedagogical approach with attention to individual students' needs clearly parallels Tarone's life long dedication to identifying and meeting the local needs both of language teachers-in-training in her classrooms and of L2 students in their classrooms, as demonstrated by her early book, *Focus on the Language Learner* (Tarone & Yule, 1989) to her most recent, *Exploring Learner Language* (Tarone & Swierzbin, 2009). In these works, and in her work as director of the Center for Advanced Research on Language Acquisition (CARLA) at the University of Minnesota, she has sought to engage language teachers as reflective practitioners in the study of learner language, which, in her view, lies at the core of effective language pedagogy.

Her recent work at the University of Minnesota has continued the pattern of bringing new perspective to SLA theory by taking advantage of information from related fields. The influence of Labov as well as the insights of sociocultural theorist Mikhail Bakhtin can be seen in the theory and methodology of Tarone's approach to variationist SLA, for example, in eliciting vernacular speech through language play (Broner & Tarone, 2001). Her groundbreaking research with illiterate and low-literate adult L2 learners in the Somali immigrant community includes Tarone, Bigelow, and Hansen (2009) and Bigelow, delMas, Hansen and Tarone (2006), winner of the 2007 TESOL/Heinle Distinguished Research Award. This research team applied concepts from cognitive psychology and neuropsychology to show that alphabetic print literacy affects adults' processing of oral L2 input, specifically that low-literate adult learners have more difficulty accurately recalling oral morphosyntactic recasts than do learners with higher levels of literacy. Studies with this previously under-researched population have broadened the view in the SLA field regarding the human capacity for language processing and acquisition.

Elaine Tarone has played a key role in bringing the fields of sociolinguistics and SLA together with a focus on the language learner as a social individual. In doing so, she, together with her fellow researchers, has expanded the SLA research enterprise to include less commonly studied L2 learners in a variety of authentic social contexts, and thus greatly contributed to the universality of SLA theory.

Task-Based Assessment

GEOFF BRINDLEY

Task-based assessment (TBA) is defined by Brindley (1994, p. 74) as “the process of evaluating, in relation to a set of explicitly stated criteria, the quality of the communicative performances elicited from learners as part of goal-directed, meaning-focused language use requiring the integration of skills and knowledge.”

TBA can be classified as a form of performance assessment which focuses on actual performance of practical skills rather than abstract knowledge (Wigglesworth, 2008). Thus, assessment in a task-based approach to language teaching is concerned with establishing how well learners are able to mobilize language to achieve their communicative goals, rather than examining their knowledge of language systems and structures.

The design of task-based tests and assessments usually begins with the identification of the real-world language use tasks that learners will need to carry out in order to achieve their communicative purposes (e.g., writing an essay, ordering a meal, understanding spoken instructions, etc.). This is followed by a description of the key performance features that will be elicited by the tasks (e.g., fluency, grammatical accuracy, breadth of vocabulary, etc.). Rating scales containing these features are then constructed that enable judges to grade the quality of testees’ task performance in the assessment situation. The resulting information on task achievement may be reported to relevant audiences in a variety of ways, ranging from simple numerical scores to complex descriptive profiles. For example, a global rating or level for the skill(s) involved may be reported in general terms (e.g., “basic user”) which may then be referenced to more detailed qualitative descriptors of performance (e.g., “can ask and answer simple questions in areas of immediate need”). In some assessment systems, ratings for particular tasks may be combined to create a numerical score for the language skills assessed; in others, achievement may be reported as a list of “can do” statements that describe the specific language-related tasks that the learner is able to carry out.

Approaches to TBA

Bachman (2007) describes two approaches to TBA. The first of these is based on the view that the inferences that we want to make on the basis of task performance are about the underlying abilities that the testee possesses. Thus, if we administer a speaking task to a learner (e.g., giving a presentation in class), the information elicited by the task would be used to make inferences concerning the construct of “speaking ability.” In establishing the dimensions of the task and specifying rating criteria, linguistic elements such as control of grammar and vocabulary or topic development would therefore usually figure prominently. In contrast, the second approach to TBA focuses on what the testee can actually *do* rather than on the abilities they possess, that is, on how successfully they can perform the actual task. Here, as Long and Norris (2000, p. 60) point out, “the construct of interest is the task itself.” In this case, the information from the example of the speaking assessment task above would be used principally to predict future performance on similar real-life tasks, and “real-world” criteria—not always linguistically based—might be used in rating testees’ performance. For example, continuing the above example of the class presentation,

2 TASK-BASED ASSESSMENT

the assessor might be interested in factors such as the degree to which the speaker was able to convey key factual information or use techniques for holding the audience's attention. While these aspects of the performance are indirectly dependent on language use, they also involve other "nonlanguage" factors.

The existence of these two approaches highlights the importance of being clear about the types of claims we want to make on the basis of the results of TBA, and constructing the task specifications and assessment criteria accordingly. In some cases, such as foreign-language-learning contexts where it is difficult to specify learning purposes and contexts in advance, assessment tasks may be used as indicators of general language ability. On the other hand, where communicative goals are clearer, such as language learning for vocational or other specific purposes, information from TBA can serve as a basis for inferences about testees' ability to perform similar tasks in the real world. However, as Kim (2004, p. 2) comments, "regardless of which approach is to be taken, appropriate tasks for the assessment need to be selected and their characteristics thoroughly described."

Advantages of TBA

Using tasks as a basis for assessment has a number of advantages, particularly where classroom assessment is concerned (Brindley, 1994):

- It focuses teachers' and learners' attention on language as a tool for communication rather than on language knowledge as an end in itself.
- It enables assessment to be integrated into the learning process through the use of attainment targets which are directly linked to course content and objectives.
- It enables learners to obtain useful diagnostic feedback on their progress and achievement, since clear performance criteria are provided against which they can compare their performances.
- It facilitates better communication between users of assessment information (e.g., potential employers) and educational institutions through the use of various forms of outcome reporting which are couched in performance terms and are hence intelligible to nonspecialists.

Issues and Problems in TBA

Despite these advantages, TBA is not without its problems, both theoretical and practical. In particular, concerns have been expressed relating to the validity and reliability of some forms of TBA, and the practical constraints involved in its implementation (Brindley, 1994, 1998a; Norris, Brown, Hudson, & Yoshida, 1998; Wigglesworth, 2008). Let us look at these briefly in turn.

Validity and Authenticity

One of the main concerns surrounding the validity of TBA involves the issue of authenticity. Since task-based assessments attempt to replicate authentic language use situations that the language learner would encounter in "real life," it is tempting to see them as valid by definition: if we want to find out how language learners can speak a foreign language, it seems logical to put them in a situation that requires them to speak. However, language-testing researchers have pointed out that this assumption of "automatic validity" is open to question on a number of grounds (Bachman, 1990, 2007). In the first place, an assessment activity is by definition an artificial situation: no matter how realistic the task is, people

still know they are being assessed under special conditions (Spolsky, 1985), and their performance may not be the same as it would in real life. A second problem with “authentic” assessment tasks is the difficulty of generalizing from a one-off performance to other situations of language use. Although a language learner may demonstrate competence in one context (e.g., responding to questions in a face-to-face interaction with a sympathetic teacher), this skill may not transfer to other contexts (e.g., negotiating a problematic transaction with an unsympathetic public official). Addressing this issue, Bachman (1990) argues that authenticity lies not only in the surface resemblance between assessment tasks and real-world behavior but also in the extent to which different areas of language skills and knowledge are sampled in the task. This is what he refers to as *interactional authenticity*. In order to construct valid “authentic” tests of communicative language ability, Bachman suggests that test construction needs to be based on a theoretical framework which includes the language abilities of the test taker as well as the characteristics of the testing context. Thus, continuing the example given above, in constructing an oral test, the test developer needs to start with an idea of what is understood by “speaking ability,” what its components are, and which of these components are to be assessed, drawing on our best current understanding of the nature of the ability or abilities in question. However, factors that affect the context in which the language will be used (such as the setting, interlocutors, channel of communication, etc.) also need to be taken into account. In this way, a sampling frame can be developed which reflects a variety of contexts of language use and enables test users to see which different ability components are being sampled by which tasks.

Validity and Construct Definition

A second concern about TBA relates to construct definition which refers to the act of specifying the nature of the abilities that are the object of assessment and identifying a set of criteria according to which learners’ performance can be rated or scored. A range of different approaches—some empirical, some not—have been adopted to task specification and identification of rating criteria. These include:

- “Expert judgment” approaches whereby suitably qualified individuals such as content experts or teachers are asked to identify the key features of learner performance that are involved in particular tasks.
- Theory-based approaches which use theoretical models of language ability such as the Bachman (1990) and Bachman and Palmer (1996) frameworks as a basis for defining the test construct and selecting the performance tasks that will be used.
- The use or adaptation of existing proficiency-rating systems and scales that attempt to describe and quantify language performance.

Each of these approaches has its drawbacks. Expert judgment approaches have been questioned on the basis that it is difficult to elicit appropriate and usable descriptions of language behavior from “experts” such as teachers or employers (Griffin & McKay, 1992). A further problem with this approach relates to reliability. Evaluating the quality of language performance is a highly subjective process, and even judges who have undergone extensive training may still disagree, making it difficult to obtain the high levels of rater agreement that are traditionally demanded in high-stakes situations (McNamara, 2000). In addition, from a practical perspective, gathering and analyzing data from expert judges involves considerable time and expense, and might not be a feasible option for many educational institutions.

Theoretical models of language ability are also open to question on a number of theoretical and practical grounds. Not only is the relationship between the elements of

4 TASK-BASED ASSESSMENT

composite models such as that proposed by Bachman and Palmer unclear, but also the complexity of such models makes it difficult for test developers to adapt them to practical test situations, as Bachman himself acknowledges (2007, p. 69). In addition, according to some testing researchers, the failure of such models to specifically incorporate the social dimensions of interaction (for example, the role of the interlocutor in oral interaction) means that they provide an incomplete account of the elements that are involved in real-life communication (McNamara & Roever, 2006).

In view of the potential problems involved in using expert judgment approaches and theoretical models as a basis for developing TBA, it is not surprising that many test developers opt for the easiest way to define assessment criteria and describe language performance by turning to existing rating systems, either in unmodified or adapted form. Many such systems are used in a wide range of language-learning contexts for describing and assessing language performance, and range from large-scale transnational curriculum and assessment schemes such as the Common European Framework of Reference (CEFR, Council of Europe, 2001) to more localized frameworks and scales that target the proficiency requirements of particular populations. However, these too have been subject to critique from both a theoretical and political standpoint. In the first place, very few have been developed or validated empirically, leaving some doubt as to the accuracy with which the scale descriptors reflect actual learner performance (Brindley, 1998b). Hudson (2005, p. 218) suggests that even scales that claim to be empirically based, such as those used as part of the CEFR, present only a partial picture of the complex range of factors that make up language ability. A further concern with frameworks and scales relates to their implementability. In this regard, it has been pointed out that educational authorities have in some cases introduced task-based curriculum and assessment frameworks and scales without providing adequate levels of infrastructural support to enable teachers to understand and apply the assessment tools (Eckes et al., 2005). This raises the critical issue of practicality, to which we now turn.

Practicality

There is no doubt that TBA is extremely time-consuming and, by extension, expensive compared to standardized indirect modes of assessment that require no human scoring. Developing and piloting assessment tasks, eliciting and rating individual performances, training (and retraining) interlocutors and raters, conducting moderation sessions, and creating and maintaining task banks is a much more complex and resource-intensive exercise than administering traditional discrete-point tests. In addition, TBA makes considerable demands on teachers, not only in terms of time but also of skills, particularly in cases where they are the principal agents of assessment and are responsible for constructing their own tests or tasks. For practitioners, the introduction of a new assessment system constitutes a major change event and the importance of support in terms of time, funding, and resources cannot be overestimated. A major investment in professional development and associated infrastructure is therefore necessary if teachers and learners are to obtain the maximum benefit from the use of TBA (Brindley, 1998a).

Conclusion

With economic globalization has come an increased focus on the functional communication needs of an increasingly mobile international workforce. The rationale for task-based approaches to language learning is thus now more obvious to educational policy makers than it was a decade ago. Around the world, TBA is increasingly being adopted at a system level in a wide range of educational contexts in which “traditional” public examinations

had previously dominated. Although some of the problems discussed in this entry have arisen during implementation, there is some evidence to suggest that if carefully planned and appropriately resourced, the integration of TBA procedures into the curriculum can be achieved in a way that enhances both teachers' and learners' confidence while at the same time improving opportunities for learning (see, for example, Davison, 2007).

However, the key challenges identified in this entry remain. In the first place, in relation to the validity question, a lot more work needs to be done in order to develop assessments which reflect current theories of language learning and language use, and which are based on empirical analyses of actual learner performance (Fulcher, 2008). At the same time, as far as reliability is concerned, if TBA is to have public credibility, a considerable investment will be required to develop and maintain systems for ensuring consistency in the way in which performances are judged. Finally, at a practical level, the adoption of TBA may necessitate a reconceptualization of the purposes of assessment on the part of the various stakeholders who are involved in language-learning programs. Teachers and learners will need to become accustomed to thinking of language tasks not simply as activities but also as indicators of progress and achievement. Learners will thus need to understand the criteria according to which their performances will be judged and to learn how to use feedback from assessment to improve their performance. This, in turn, will necessitate a closer examination of the components of language tasks and a raising of learners' awareness of how language functions to achieve particular communicative purposes. As far as other "consumers" of assessment information are concerned (e.g., parents, employers, educational administrators), the reporting of task performance means that they will have to be educated to accept assessments that are complex and multidimensional, rather than traditional test scores. This will not be easy, and will necessitate close cooperation and continuing dialogue between all of the stakeholders involved in language programs.

There is no doubt that TBA in language learning is firmly established at the level of the classroom where it has demonstrated the potential to bring about significant improvements in the quality of learning. As it moves into high-stakes areas such as certification and selection, however, it remains to be seen whether the benefits will be perceived to outweigh the considerable costs involved. In this regard, it is to be hoped that the value of TBA will be as evident to those outside the classroom as it is to those within it.

Task-Based Learning: Cognitive Underpinnings

PETER ROBINSON AND ROGER GILABERT

Over the past thirty years, proposals for task-based language teaching (TBLT) have drawn on a variety of claims about, and research into, the cognitive processes thought to promote successful second language acquisition (SLA). A brief overview of these will be given below. They reflect a shift from a concern with how TBLT can facilitate comprehension of input, to how it can facilitate interaction and attention to output, and the development of increasingly target-like speech production. They also reflect the progressively sophisticated knowledge that SLA research has provided concerning cognitive processes such as implicit, incidental, and explicit learning, and automatization of knowledge.

Cognitive Processes in Task-Based Learning

In his account of the theoretical motivation for the task-based “procedural syllabus” Prabhu (1987) argued that: “task-based teaching operates with the concept that, while the conscious mind is working out some of the meaning-content, a subconscious part of the mind perceives, abstracts, or acquires (or re-creates as a cognitive structure) some of the linguistic structuring embodied in those entities, as a step in the development of an internal system of rules” (pp. 70–1). Prabhu’s cognitive rationale for TBLT is thus compatible with Krashen’s (1982) claim that *comprehensible input* is necessary for learning, and that it promotes incidental learning of a tacit, implicit knowledge base. Long (1985) argued that the *interaction* that task work promotes is additionally important since it provides one way in which input can be made comprehensible, as well as a context for attending to problematic forms in the input and output during task work. Consequently, Pica, Kanagy and Falodun (1993) described a taxonomy of task characteristics in order to promote further research into which of these characteristics optimally promoted interaction work. Swain (1985) argued that attention to *output* produced during task performance could additionally facilitate SLA, since it provided a context for comparing the speaker’s performance with an interlocutor’s, and noticing gaps and mismatches between them, and for hypothesis testing about the formal means for expressing meanings and communicative intentions in the second language (L2).

Skehan (1998) provided the first detailed *psycholinguistic* rationale for the effects of some aspects of task demands on learning and performance, focusing in particular on the extent to which having time to plan a task led to increases in the *accuracy, fluency* and *complexity* of speech produced, when compared to performance on tasks where planning time was not available. Robinson (2001) also provided a psycholinguistic rationale for how *cognitive complexity* can be increased along two broad dimensions of the demands made by tasks, and claimed that these would have distinct influences on learning and performance. Increasing demands on “resource-directing” dimensions, he argued, directs learners’ attention to aspects of language used to structure increasingly complex concepts, facilitating awareness of how these concepts are differentially encoded in the L2, so prompting L2

development. Along these dimensions, initially *implicit* knowledge of the L1 concept-structuring function of language (see Talmy, 2000) becomes gradually *explicit*, and available for change, following a natural developmental order reflected in the sequencing decisions. In contrast, along “resource-dispersing” dimensions, increasing task demands has the effect of gradually removing processing support (such as planning time) for access to current interlanguage, and thus practice along them requires, and should encourage, faster and more automatic L2 access and use. Along these dimensions, therefore, improvements in performance will involve initially explicit knowledge becoming more automatized.

Design Characteristics Affecting the Cognitive Processing Demands of Tasks

Current research into the cognitive underpinnings of TBLT is focused on the effects that design characteristics of tasks have on the cognitive processes that facilitate L2 production and learning. Some of the design characteristics of tasks that have received the most attention from researchers are described below.

Planning Time

There have been many studies of how tasks can be made easier for second language learners by giving them time to plan what they will do or say in the L2 (Ellis, 2005). This is perhaps the area that has received the most attention by SLA researchers interested in tasks, and it has clear implications for effective pedagogic decision making. In general, the studies that have been done seem to show that having time to plan a task increases the accuracy, fluency and complexity of learner language.

Single/Dual Tasks

Another dimension of task complexity that is similar to this is the single–dual task dimension. It is much less complex to answer a phone call in the L2, than it is to answer a phone call and monitor a TV screen at the same time, to check the weather, or changes in exchange rates, for example (Robinson, Ting, & Urwin, 1995). The latter, dual task, disperses learner attention over a number of L2 stimuli. In general, tasks made complex on this dimension also lead to poorer accuracy, fluency, and complexity of performance.

Intentional Reasoning

In contrast to the above dimensions of task complexity, other task characteristics may direct learners’ attention to the language needed to meet complex task demands. On these dimensions Robinson (2001) argued that increasing task complexity should lead to more accurate and complex learner language, over time. However, complex tasks on these dimensions also negatively affect fluency. For example, in L2 English, tasks which require complex reasoning about the intentional states that motivate others to perform actions can be expected to draw heavily on the use of cognitive state terms for reference to other minds—*she suspected, realized, etc.*—and in so doing orient learner attention to the complement constructions accompanying them—*suspected that, wonders whether, etc.*—so promoting awareness of, and effort at, complex L2 English syntax (Robinson, 2007; Ishikawa, 2008).

Spatial Reasoning

Another example of resource-directing task demands are those tasks which require complex spatial reasoning, and articulation of this in describing how to move, and in what

manner, from point A to point E, by way of intermediary landmark points B, C, and D, etc. These can be expected to draw heavily on the use of constructions for describing motion events (Cadierno, 2008). Such tasks therefore have the potential to promote awareness of lexicalization patterns in L2 English for describing these motion events, in which motion and manner are typically conflated on verbs (e.g., *rushed*) and paths are expressed outside the verb in satellites that conflate a number of motion events (e.g., *rushed out of the house, down the street and into the post office*). English lexicalization patterns are different from those in Japanese, where motion and path tend to be conflated on verbs, and manner encoded separately (e.g., *isoide haitta*). Consequently, Japanese makes much less use of event conflation in reference to motion than English does. So a task requiring complex spatial reasoning (giving directions from a large map of an unknown area) may prompt Japanese L2 learners of English to revise their preferred ways of referring to motion, in line with English lexicalization patterns (Cadierno & Robinson, 2009).

Here-and-Now/There-and-Then

In yet a different conceptual domain, tasks requiring reference to events happening now, in a shared context (here-and-now) orient learner attention to morphology for conveying tense and aspect in the present, compared to events requiring much more cognitively demanding reference to events happening elsewhere in time and space (there-and-then). There-and-then tasks require greater effort at conceptualization (since events are not visually available in a shared context) and greater demands on memory (Gilbert, 2007). One effect of performing tasks on this dimension is to draw learners' attention to the morphological forms and phrases that can be used to refer to the present and the past in English, and these are needed to help them perform the tasks. The morphology for referring to the past in English is much later acquired by L2 learners than the morphology for referring to the present, so complex tasks may promote learner attention to, and use of, this later acquired past tense morphology. That is, in this and other cases of increasing the complexity of resource-directing demands of tasks, Robinson's "cognition hypothesis" (2001) predicts more "noticing" of L2 forms (Schmidt, 2001), more uptake and incorporation of them, as well as increasing accuracy and complexity of production on complex compared to simpler task versions.

Effects of Cumulative Increases in the Cognitive Demands of Tasks

To date, the effects of the design characteristics of tasks contributing to their cognitive complexity (as described above) have often been contrasted for their distinct effects on learning and performance. However, for TBLT a key issue is the cumulative effect of increasing the complexity of pedagogic task demands, so as to gradually approximate the full complexity of real-world, target-task performance (Long & Crookes, 1993). With this in mind, Robinson (2005) has made the following theoretical claims about the effects of cumulative influences in the demands of tasks on cognitive processes thought to facilitate SLA. Some of these claims are the focus of current research, while others remain issues for future research.

Output

The first of these claims is that increasing the cognitive demands of tasks contributing to their relative complexity along resource-directing dimensions (e.g., from – to + intentional reasoning demands) will push learners to greater accuracy and complexity of L2 production in order to meet the consequently greater functional/communicative demands they

4 TASK-BASED LEARNING: COGNITIVE UNDERPINNINGS

place on the learner. That is, greater effort at conceptualization will lead learners to develop the L2 linguistic resources they have for expressing such conceptualizations. Some research findings support this claim (Robinson, 2007; Ishikawa, 2008). Related to this first claim is the prediction that increasing task demands will lead to a higher number of interactional episodes (e.g., language-related episodes, clarification requests, or recasts) which are known to push second language development. Some studies have provided evidence of such a claim (Robinson, 2007; Gilabert, Barón, & Llanes, 2009).

Uptake

The second claim is that cognitively complex tasks promote heightened attention to and memory for input, so increasing learning from the input, and incorporation of forms made salient in the input. So, for example, there should be more uptake of oral recasts on complex tasks, compared to simpler tasks, or more use of written input provided to help learners perform tasks. Some research findings support this claim (Revesz, 2009; Baralt, 2010).

Memory

Related to this, the third claim is that on complex tasks there will be longer-term retention of input provided (e.g., in the form of written prompts, or oral feedback) than on simpler tasks. There are currently no studies that have addressed this claim.

Automaticity

Fourth, the inherent repetition involved in performing simple to complex sequences will also lead to automaticity and efficient scheduling of the components of complex L2 target-task performance, compared to target tasks performed without the benefit of such pedagogic task sequencing. This should be revealed in estimates of the fluency with which target tasks are performed following a sequence of increasingly complex pedagogic tasks (as manifested by fewer incidents of self-repair, fewer hesitations, etc.), as well as in criterion-referenced measures of the extent of successful target-task performance. There are currently no studies that have addressed this claim.

Aptitudes

Fifth, individual differences in affective and cognitive abilities contributing to perceptions of task difficulty will increasingly differentiate learning and performance as tasks increase in complexity. This is likely to be an intense area of future research, since it can reveal much about the cognitive processing prerequisites for successful task-based learning and performance, and since it will ultimately be desirable to match individual profiles in task aptitudes to those conditions of task performance that learners are best suited to, in order to optimally facilitate TBLT outcomes for learners. In line with this claim, Robinson (2007) found that greater output processing anxiety led to less complex speech production on complex tasks (with intentional reasoning demands), compared to those with lower output anxiety, but these differences in output processing anxiety had no effect on complexity of speech produced on simple tasks (without intentional reasoning demands). On the other hand, examining the same task complexity differential, Baralt (2010) found that individual differences in working memory capacity did not predict greater accuracy, fluency or complexity in performance on complex versus simpler task versions. Robinson (2010) describes individual, task aptitude measures that could profitably be used in future studies of this issue.

Teacher Education for Language for Specific Purposes

DAVID R. HALL

Introduction

The teaching of language for specific purposes (LSP) has a very long history, found in various forms in ancient China and in ancient Greece. A key difference between the ancient and modern teachers of LSP, however, is that the ancients were teaching language in and for a context that they themselves had already mastered. Teachers of rhetoric, of legal language, and of courtly discourse were expert practitioners, passing down their expertise to apprentices. By contrast, modern teachers of English for electronics, Spanish for marketing, Japanese for business, or Chinese for civil engineering are, with some exceptions, not members of the discourse community which they are aiming to have their students join. Most language teachers, where they have training, are trained as language teachers, not as subject specialists.

Modern LSP, most widely known initially in its English for specific purposes (ESP) manifestation and especially in that of English for science and technology (EST), became widespread in the 1970s, and was closely connected with the teaching approach known as communicative language teaching (CLT). Before the advent of LSP, in cases where language teachers did not simply become language teachers by virtue of being a native speaker of the target language, their teacher training was likely to focus on methodology, grammar, and perhaps literature. CLT brought about a genuine paradigm shift, causing teachers to foreground issues of propositional content, communicative purpose, and context, focusing, in other words, on what people wanted to say to whom in what context and with what intended outcome. The problem for LSP teachers, recognized only slowly in the development of this new paradigm, was that the focus on the learners and their intentionalities meant that teachers could no longer decide in advance what language was to be used in the classroom. Privileging learners' own purposes means relinquishing full teacher control of the classroom. LSP also, in most cases, changes the relative status of teachers and learners. Compared with the more traditional view of the teacher as the expert, LSP carries with it the concept of shared expertise, where the learners are likely to have more experience and knowledge than the teacher in the specific area being targeted. This change may of course be seen as a threat or as an opportunity, depending on the educational philosophy and personality of the teacher, and on the cultural expectations of the roles of learners and teachers in different parts of the world and in different institutions.

In these circumstances, the training of teachers for the role of specific-purpose language teaching takes on an added importance. The well-trained language teacher knows how to introduce new language structures, to get his or her learners to practice language items, to focus on accuracy, to exploit language points as they arise, to use language within fairly controlled parameters, and all the other things that language teachers routinely do. LSP teaching, however, forces teachers to go beyond their own levels of expertise and, in effect, to become researchers as well as teachers: "the dividing lines in ESP between researchers

and teachers, or curriculum designers, materials developers, and teachers, are frequently blurred. Since even the earliest days of ESP . . . practitioners have viewed assessment of specific needs as requiring research skills and creative approaches to novel situations” (Belcher, 2006, p. 135).

Content Expertise

Some language teaching operations assume that anyone who is qualified to teach languages is also qualified to teach LSP. Regrettably, this often includes teachers who have few qualifications at all, other than being native speakers. Though this is quite common in many poorer countries where English-speaking backpackers get jobs as language teachers, it often comes as a surprise to see the same practices and attitudes in relatively well-resourced institutions of higher learning in the Western world. Adamson (1997) points out that “regular” faculty working in modern language departments are reluctant to get involved in teaching languages to non-majors, and “The task of teaching these courses falls to staff in language centres, usually part-time native speakers, recruited locally” (p. 142). In his attempt to introduce specialized classes in French, German, or Spanish for science, business, tourism, accountancy, and the law, Adamson was distraught to find that such courses “are being taught . . . by native speaker tutors who are not professional language teachers and whose experience, if any, is likely to have been in continuing education and other non-academic types of teaching” (1997, p. 143).

Even where teachers are experienced and appropriately trained, there are disagreements about how much specialist training LSP teachers need. Janet Sutherland summarizes her skepticism neatly:

- ESP teaching is no different from “standard” foreign language teaching. Harumpf . . .
- ESP teaching at its best requires teachers to be fully qualified in both EFL and in the subject area. Again, harumpf. (Sutherland, 1995, p. 6)

General advice to aspiring LSP teachers often emphasizes the need for some knowledge of the specific language. One career-advice Web site has this to say:

ESP . . . is required by many businesses and is generally well paid (up to \$50 an hour). This type of position generally requires at least a Teaching Diploma and, possibly more importantly, expertise in the type of English being taught. (About.com., 2010)

It is not always clear, however, how exactly this expertise might be obtained and indeed what exactly constitutes a “type of English.” Some LSP theorists do not mention specific language at all, but talk about understanding the methods and culture of the specific content area:

It would be advantageous to develop an awareness of the principles and concepts driving the discourse community in the field. For example, if you are going to teach a group of bioscience majors, it would be helpful to know about the scientific method that guides their manner of study and research. (Kinoshita, 2006, p. 4)

At the opposite end of the scale from those who teach only by virtue of being native speakers, there are many who believe that the LSP teacher must be a fully qualified expert teacher both in the subject matter and in language. Kone (2007) goes some way toward this position when he describes the initial ESP teacher training course that he developed in the Côte d’Ivoire, going beyond his stated principle that “Basic knowledge in business,

science and technology is necessary in rendering an ESP teacher operational in nearly all technical and vocational fields" to actually providing what he calls "parallel training."

Content-based instruction (CBI) has a similar approach (Stryker & Leaver, 1997), in which language learning takes place through a primary focus on content. The "content," however, may or may not be related to a specific learning purpose; the approach may, for example, use topics that are of general interest to the particular group of learners in the classroom. The proponents of content and language integrated learning (CLIL) go much further, suggesting that CLIL teachers must have expertise in language and in pedagogy, while having a parallel level of expertise and a primary focus on content to be taught as part of the regular syllabus. In CLIL, classroom practice must fully integrate all three elements: content, language, and pedagogy:

Teachers undertaking CLIL need to develop multiple types of expertise: among others, in the content subject; in a language; in best practice in teaching and learning; in the integration of the previous three; and, in the positioning of CLIL within an educational institution. (Marsh, Mehisto, Wolff, & Frigols Martin, 2010)

Context Expertise

While many LSP situations will likely not fall under the CLIL, or even the CBI, umbrella, this last quotation already hints that adequate teacher training involves much more than language teaching methodology and knowing something about the specific-purpose topic, when it mentions the "positioning" of the endeavor within the wider institutional context. LSP operations will always involve groups of diverse stakeholders. These include, naturally, the language teachers and learners, but they also involve other teachers, work colleagues, head teachers, line managers and supervisors, and, above all, the purse-holders—those who are funding the operation. Managing relations with all of the different groups, especially where the operation involves changes to existing practices, is a skill that the LSP teacher has to develop. Among the management issues that confront the LSP teacher are that the perceptions of what is needed may differ between stakeholders; that there may be different opinions on what constitutes evidence of the success of a course; that different groups might have quite different agendas; and that the status of the LSP teacher has to be established and maintained at a high enough level to ensure efficient delivery of the course with adequate resourcing of time, personnel, equipment, and space. As many LSP teachers, particularly in the private language school sector and in pay-for-service operations, will also need to negotiate contracts with the purse-holders, training in financial management is also necessary.

On the issue of what constitutes specific-purpose language, it is clear that the concept has undergone a major change since the early days of modern LSP, when the emphasis was on analysis of language as text. Analysis of whole texts (as opposed to isolated sentences) was a change that resulted in a more multifaceted examination of the text, involving not just the text as a stand-alone object for analysis but also the users of the text, the uses to which the text is put, the context in which the text is generated and received, the relationship between the text and other texts, and the actions that ensue from use of the text. This has resulted in practitioner-researcher attention being turned to sociological macro-issues such as power relationships, identity, group structure and membership, and "other considerations of what it means to be able to use the resources of a language effectively in a whole variety of social, cultural, economic, political, professional, personal and institutional contexts" (Hall, *in press*).

The work of sociologists such as Derek Layder (1993, 1997) has been particularly influential, with its focus on the link between research and practice and its privileging

of multi-perspective analytical approaches. Such approaches have underpinned much recent analytical work in language, for example Bhatia's four-space model (2004, pp. 18–22), Candlin and Crichton's model of interdiscursivity (Candlin & Crichton, 2010; Crichton, 2010), and Wodak's extensively contextualized analytical procedures (Wodak, Muntigl, & Weiss, 2000).

It is clear that the budding LSP teacher and course designer will need to understand and be able to deploy various discourse analytical techniques if we are to avoid the situation, common in earlier LSP practice, where the analyst took an outsider's perspective only, without understanding how the discourse, its stages, and its motivations were perceived by others. The practice of LSP is littered with examples of the language teacher making unwarranted assumptions about communication practices in the technical area concerned (see Swales & Feak, 2000, for an example of the different ways lawyers and language teachers interpreted case-study texts).

Essential Knowledge and Abilities

We are now in a position to be able to attempt an inventory of what might be included in a training course for LSP teachers.

First of all, in seeking to become a teacher of LSP, the novice must be able to examine and reflect on each of the components of the acronym itself.

- *Language*: How can it be said to be specific? In what terms can its specificity be identified and analyzed? What kinds of analysis will be useful? How comprehensive does such analysis need to be? Do all stakeholders have similar ideas about what language is, how it works, and how proficiency is measured?
- *Specificity*: How specific can we be? What trade-off is there between effectiveness (more specific?) and efficiency (less specific?)? In "selling" the course to decision makers, what part will specificity play, and what compromises need to be made?
- *Purposes*: Whose purposes? How immediate are the purposes? At what point can we measure whether the purposes have been fulfilled?

In addition, the practitioner needs to be an effective teacher, to have a view about how languages are taught and learned, to know what different classroom practices are available, to understand how success might be measured, to manage classrooms, to devise appropriate materials and activities, to structure both individual classes and entire programs—in short, to have all of the other features common to any successful teacher.

But the LSP teacher also needs training in management, particularly in change management, people management, negotiation skills, time management, and financial management. We might also mention here skill in public relations, or what is sometimes referred to as "impression management," whether operating in a commercial language school, where repeat business is a necessity for economic survival, or as part of a larger operation such as a public school or a university, where the status of the LSP teacher is a major consideration both in obtaining adequate resources and in establishing productive collegial relationships with content teachers and senior decision makers. Establishment and maintenance of respect for the professional credibility and integrity of the course provider are important both in workplace training and in academic contexts, whether in the private or public sector. Marginalization of the language experts within larger organizations has been and continues to be a major issue, having a particular impact on recruitment and appropriate remuneration of suitably-qualified practitioners.

This inventory might be grouped into three major areas that one would expect to see in any teacher-training course for LSP:

- pedagogy,
- context-embedded language and discourse analysis, and
- management.

There are several universities around the world that offer named postgraduate degrees in LSP (or its variants) or elective specializations within broader degrees in language teaching or applied linguistics. There are also many short courses run by the public and private sectors. Many such courses are now available in distance or online modes. There are several specialist publications (such as *English for Specific Purposes*, *English for Academic Purposes*, *GERAS* (in French), *International CLIL Research Journal*), organizations (such as the Asia-Pacific Rim LSP and Professional Communication Association), conferences (such as the European LSP Symposium), and special interest groups of larger organizations and societies (such as the IATEFL ESP SIG and the TESOL ESP interest section). The Web allows access to a rich array of resources for LSP teacher training, including sites offering lesson plans, practical classroom activities, and discussion forums for the exchange of ideas.

Teacher Education for Multilingual Education

OFELIA GARCÍA AND TATYANA KLEYN

If, as García (2009, p. 5) states, “bilingual education is *the only way* to educate children in the twenty-first century,” then *all* teachers must be prepared both to advance the plurilingual competencies of students, as well as teach students with different home language practices and bilingual abilities. With the increased movement of people, goods, and information brought about through globalization, the world’s classrooms are becoming more diverse in every way. It is difficult today to find a teacher in any part of the world who is not faced with a multilingual classroom. Some classrooms are multilingual because the children have home language practices that differ from those of school. Other classrooms are multilingual in that the purpose of instruction is precisely to make children bilingual or plurilingual. Thus, all teacher education programs in the 21st century must prepare teachers for multilingual education. No longer can a specialist, such as a second language teacher or bilingual educator, be solely responsible for the education of bilingual students who either speak multiple languages or who are learning an additional language in school.

Throughout the world most teachers are initially educated at tertiary institutions, either teacher training colleges or universities. Often these teacher education programs follow traditional disciplinary divisions whereby teachers are trained as specialists in a particular field. Although each area may have its own body of literature, professional organizations, and teacher certification areas, few opportunities exist for prospective teachers to learn across specializations. Usually issues related to educating *emergent bilingual students*, whether language minorities learning a dominant language or language majorities learning additional languages (García & Kleifgen, 2010), are relegated to those specializing in language or bilingual teaching. And yet, it is increasingly important for all teacher educators to become knowledgeable about issues surrounding the education of emergent bilinguals, that is, those who are acquiring an additional language, and bilingual students, those who are already speakers of more than one language. This requires increased collaboration between teacher educators in different content areas and specialists in bilingualism in education. However, this does not mean that teacher education should cease to prepare teachers for particular subjects, for specialized teachers will always be needed. What this means is that in many ways all teachers in the 21st century need to be prepared to be bilingual teachers (Adelman Reyes & Kleyn, 2010); that is, they need to see themselves as building on and developing the students’ additional languages whilst educating them.

Of course, teacher education is not limited to tertiary education, for professional development throughout a teacher’s career is never-ending. This is because of the dynamism of life itself, changes in sociopolitical contexts, variations in conceptions of knowledge, as well as teaching and learning, technological and instructional material innovations, and the constant transformation of students themselves. All teacher education programs, whether at tertiary institutions or those that take place in local teacher unions and centers or local schools, must have a curriculum that develops three strands of competencies: (a) understanding about bilingual students and their families, especially students from language minority backgrounds; (b) knowledge of language and bilingualism/multilingualism;

and (c) awareness of how to deliver a pedagogy for multilingualism. But in order to develop understanding of these strands, which we elaborate upon below, these topics cannot be simply taught in a traditional manner. Instead, teacher education programs must find ways to have prospective teachers interact directly with emergent bilingual students, their families, communities, and classrooms to construct their own insights and ways of teaching. Here we review three ways of delivering this situated-teacher education preparation previously identified in García (2008): (1) descriptive reviews, (2) micro-ethnographies, and (3) direct experience in schools.

Descriptive reviews develop teachers' abilities to pay close attention to, as Carini (2000, p. 11) says, "the child in motion," that is, the bilingual child engaged in learning activities that are meaningful. Furthermore, descriptive reviews develop teachers' abilities to use language descriptively through cases and examples, while avoiding judgmental or evaluative language. These descriptive reviews are an important foundation for multilingual education, as close attention is paid to children's physical, emotional, cognitive, and learning characteristics, while noticing the child's language practices, as well as those of the teacher. Thus, the review combines the holistic education of the child with language and bilingual development. Because bilingual students live in communities that are often different from those of teachers and the school, descriptive reviews of students are not sufficient to develop the capacity needed for multilingual education. Instead, the observational and descriptive language use skills developed through descriptive reviews have to be applied to *micro-ethnographies* of communities and families in which all teachers partake—that is, teachers have to become ethnographers, as they learn to broaden their observational skills from the child to the community. Participating in the larger community allows all teachers, but especially those who may be outsiders to the communities where their students live, to have a better sense of the community's funds of knowledge (Moll, Amanti, Neff, & González, 1992) and to understand cultural and linguistic contexts to inform their curriculum and pedagogy. Finally, there is no coursework or workshop for teacher preparation that can substitute for *direct experience* with multilingual students and their families in schools. All prospective teachers need to be immersed in school life early, to observe teaching, and to eventually participate in assisted teaching and assisted assessment of student learning with an experienced mentor (Hawkins, 2004). One way of making direct experience an integral part of teacher education is to build collaborations between teacher education programs and local schools with strong bilingual/multilingual programs and a large multilingual population. Professional Development Bilingual Schools (PDBS) provide a setting in which prospective teachers can experience good practices with regard to developing bilingualism and paying attention to the different home language practices of students under the tutelage of experienced teachers.

The first strand of a teacher education curriculum for multilingual education must be to develop *understandings of bilingual students and their families*. All teachers need to be able to observe bilingual children closely and describe them engaged in meaningful learning activities. Teachers also need to be able to understand what sets the child in motion, an understanding which spans beyond the learning activities of the school to the child's home and community life. Teachers need to become knowledgeable of the many home language and cultural practices of the children, and be able to build on that knowledge not only to engage with individual children, but also to share it with all the children in the multilingual classroom. To build this knowledge, collaboration with families is key. For example, the *language awareness programs* established by Hélot and Young in Alsace (2006) brought multilingual families into classrooms where all the children were exposed to the cultural and linguistic backgrounds of their peers.

Beyond linguistic and cultural information, teachers need to develop a sociopolitical consciousness about the nature of the linguistic diversity of the children and the languages

they are trying to promote. They should be able to answer the following questions: Are the children immigrants themselves? Children of immigrants? Autochthonous minorities? Indigenous peoples? Autochthonous majorities? If immigrants, were their parents voluntary or involuntary minorities? What is the group's sociohistorical association with the society? What are the children's individual sociolinguistic profiles, as well as that of the ethnolinguistic group to which they belong? How does the group fare with regard to social class structure? Is the group structurally incorporated in the economy? How does the group's language rank in terms of linguistic hierarchies? Has the ethnolinguistic group experienced language loss or language shift? What has been their success in language maintenance or language acquisition? Has the ethnolinguistic group experienced racism or linguisticism? In the past or in the present? Teachers then need to act on all this information by constructing curricula and pedagogies (see below) that build on the sociopolitical and sociolinguistic profiles of the children in question.

A second strand of a teacher education curriculum for multilingual education has to do with *knowledge about language, bilingualism, and language acquisition*. Teachers need to be cognizant of basic sociolinguistic and psycholinguistic essentials (Hawkins, 2004; Bartels, 2009). They should understand that academic language is a product of standardization and has little to do with the languaging, that is, language practices, at home. And they should understand that all languages have been socially constructed and are products of valuing based on their social and political power. Literacy, as Street (2005) has shown, is not a monolithic construct made up of a discrete set of skills, but involves *social practices* that are embedded in a web of social relations that maintain asymmetries of power. Thus, learning academic language is not a neutral activity.

With regard to bilingualism, prospective teachers need to recognize it not as a "problem," but rather as a "resource" (Ruiz, 1984) for individual learning, group learning, and society at large. It is important for teachers to understand the cognitive benefits of bilingualism and biliteracy—the analytic orientation to language known as greater *metalinguistic awareness* (Bialystok, 2007), the flexible perceptions and interpretations of heightened *divergent or creative thinking*, and the greater practice in gauging communicative situations, giving bilinguals increased *communicative sensitivity* (Ben-Zeev, 1977).

All teachers should also be familiar with Jim Cummins's work on the relationship of a student's home language and the development of an additional language. Cummins's concept of *linguistic interdependence* and his related theoretical construct of *common underlying proficiency* posit that both languages bolster each other in the student's acquisition of language, literacy, and knowledge (Cummins, 1981). Teachers of multilingual classrooms need to be especially sensitive to the difference between what Cummins calls *basic interpersonal communication skills*—surface fluency in conversational language or in writing supported by cues that have little to do with language itself (gestures, repeating, providing examples)—and more abstract decontextualized language, or, in Cummins's terms, *cognitive academic language proficiency* (CALP), which is needed for most school tasks. Teachers should also be aware that research throughout the world has shown that although emergent bilinguals can usually acquire the language of everyday communication in one to three years, it takes *five to seven years*, if not longer, to develop more abstract language abilities in an additional language.

The major social, linguistic, political, and psychological issues that surround the development of biliteracy should be explored in teacher education programs using Hornberger's *continua of biliteracy* (2002), while developing understanding that positive transfer across literacies is maximized when students are allowed to draw from all their existing languaging.

Teachers in the multilingual classrooms of the 21st century must also be familiar with the concept of *dynamic bilingualism* (García, 2009) which goes beyond the notion of two autonomous languages and of the additive or subtractive bilingualism models of the 20th

century, and instead suggests that the language practices of *all* bilinguals are complex and interrelated, rather than linear. Dynamic bilingualism refers not to languages that students *have*, but to the development of different language practices to varying degrees that students and teachers *use* in order to interact with increasingly multilingual classrooms and communities. Thus, *translanguaging* (García, 2009), the process by which students and teachers engage in complex discursive practices in order to make sense and communicate in multilingual classrooms, should be understood by the teacher. Translanguaging includes code switching—the shift between two languages in context—but differs from it in significant ways, for it includes other bilingual practices that go beyond a simple switch of code, such as the translanguaging pedagogy introduced by Cen Williams (cited in Baker, 2001), where bilingual students read in one language and then take notes, write, or discuss in another.

In the 21st century understandings about how to teach all children should be centered on the concept of multilingualism and dynamic bilingualism, as opposed to monolingualism or monoglossic conceptions of bilingualism (García, 2009). Teachers need to be made aware of the fallacy of traditional second language acquisition concepts such as first and second language, native language, mother tongue, ultimate language attainment, and fossilization. Thus, children must be viewed not just as second language learners, but as emergent bilinguals who contribute to the formation of a multilingual world.

The third strand of a teacher education curriculum for multilingual education has to do with enabling teachers to construct a *pedagogy for multilingualism*. García (2009, pp. 318–29) proposes two basic principles of a multilingual pedagogy: (1) *social justice*, including advocating for equity, promoting language affirmation, upholding rigor, having high expectations, and advocating for fair assessment; and (2) *social practice*, including quality interactions, collaborative learning, authentic situated practices, connection to students' worlds and identities, and a focus on language practices.

Teacher education programs must instill an awareness that multilingual education is one way of acting on social justice by exposing the linguistic hierarchies that determine which languages and speakers are privileged. But beyond exposure and acknowledgment, teacher education programs must develop the teachers' courage to advocate for individual students, groups, programs, and policies that favor multilingualism. Teacher advocacy can take on many forms—from educating colleagues and administrators about multilingual issues, to speaking out about inequities, to teaching students to advocate for their own linguistic, educational, and human rights.

An advocacy stance is critical when it comes to the assessment of multilingual students. The current context requires the use of monolingual tests, which lack validity for this population (Shohamy, 2005). Furthermore, any assessment, regardless of the content area, is first and foremost an assessment of the language in which it is given (García & Menken, 2006). Thus, teacher education programs need to make all teachers aware of the potentially dangerous ways that high-stakes assessments in students' nondominant languages unfairly and inaccurately portray emergent bilinguals as deficient, and to encourage them to advocate on behalf of their multilingual students.

When social justice drives teacher education for multilingual education, programs strive to support teachers in constructing a pedagogy of inclusion so that all children's home language practices are acknowledged, included, and developed. Thus, a multilingual pedagogy includes the notion of *critical care* (Rolón-Dow, 2005), encompassing authentic relationships of care and trust, while at the same time addressing the more difficult questions of otherness, difference, and power (Valenzuela, 1999). Through a critical care stance toward all students, educators can construct a pedagogy that differs from the curriculum, standards, and assessments which generally stem from mainstream values of monolingualism and monoculturalism.

Under the second principle, *social practice*, teacher education for multilingual education needs to develop teachers' abilities to collaborate. In order to support multilingualism, partnerships between content teachers and language teachers are required to ensure students are both learning content and developing additional languages. A collaborative team teaching (CTT) model can expand the ability of all educators to teach for multilingualism. The collaborative disposition of teachers for multilingualism needs to extend beyond schools by building connections with families, community-based organizations, and governmental organizations that support the use of different languages.

All teachers also need to be able to identify and create resources across languages and cultures that are authentic and representative of students in their classroom (and beyond). This includes trade books, textbooks, videos, and Web sites. The availability and visibility of such resources sends a direct message to students about the worth of their languages, and subsequently themselves.

Twenty-first-century teacher education programs for multilingual education must not only provide a curriculum for all teachers that includes these three strands of knowing about bilingual/multilingual students, bilingualism/multilingualism, and multilingual pedagogies. They must also break out of the traditional mode of delivering instruction, through the incorporation of a multilingual/heteroglossic and experiential pedagogy that allows for differences in descriptions, observations, and experiences.

Teaching a Second or Additional Dialect

JEFF SIEGEL

Definitions

The term “dialect” refers to varieties of the same language that differ from each other in vocabulary, pronunciation, and grammar, and that are associated with particular geographic regions or social groups. The learning of a second or additional dialect is referred to here as second dialect acquisition (SDA).

SDA is concerned mainly with three broad types of dialects: national, regional, and social. A national dialect is a way of speaking a language that is characteristic of a particular country—for example, Canadian, American, and Australian English and European and Brazilian Portuguese. With regard to English, an important subtype of national dialect is World Englishes, such as Indian, Singapore, and Philippine English.

Many people think of a national dialect as the “standard”—the abstracted and idealized version of a dialect originally spoken by the upper middle classes of one dominant region of the country, and later “standardized” in written form—for example, standard British English and High German. In some countries, however, the standard is a variety very different to what is spoken colloquially by most of the population. Such a situation is referred to as “diglossia” (Ferguson, 1959)—as found, for example, in Egypt with Egyptian colloquial Arabic and Classical Arabic.

A regional dialect is spoken in one particular area of a country—for example, Cockney and Liverpool English in England, and Swabian and Bavarian in Germany. A social dialect, on the other hand, is a variety of a language spoken by a particular group based on social characteristics other than geography. SDA is most relevant to speakers of social dialects that are based on ethnicity (ethnic dialects), such as African American English and Chicano Spanish. Both regional and social dialects are generally unstandardized.

Contexts for SDA

As in second language acquisition (SLA), the study of SDA can be divided into two broad contexts: naturalistic and educational. Naturalistic SDA refers to learning a new dialect (the D2) without any formal teaching. This most often occurs when people who speak a particular regional dialect as their first dialect (D1) migrate to another part of the same country where a different regional dialect is spoken—for example, speakers of various American dialects moving to Philadelphia (Payne, 1980) and speakers of rural Norwegian dialects moving to Bergen (Kerswill, 1994). Naturalistic SDA also occurs when people migrate to another country where a different national dialect is spoken—for example, speakers of American English to Australia (Foreman, 2003).

Educational SDA involves formal training. There are three different educational contexts. In the first two contexts, students are normally adults, the emphasis is on pronunciation, and instruction is generally one-to-one or in small groups. Dialect coaching involves teaching actors to speak in various national, regional, or ethnic dialects for the purpose of dramatic

2 TEACHING A SECOND OR ADDITIONAL DIALECT

performance. Dozens of dialect coaches (or voice coaches) have Web sites offering their services—often with lists of films, plays, and other productions that they have worked on. There is also an association of dialect coaches and related professionals: the Voice and Speech Trainers Association (VASTA). In addition, some educational institutions offer courses or workshops on learning dialects for acting.

Accent modification (or accent reduction) training is aimed at students who want to change their existing dialect for some reason: for example, immigrants wanting to speak the national dialect of their newly adopted country, and more commonly, speakers of regional or ethnic dialects wanting to speak a variety closer to the standard in order to improve their prospects in education or employment. One important area concerns the “call center” industry in countries such as India and the Philippines where World English varieties are spoken. To improve communication with customers from countries such as the USA and Britain, many call centers require that their employees undergo accent modification training to replace some of the more noticeable features of their variety with features of American or British English (see Mesthrie & Bhatt, 2008, pp. 216–18).

The third and most common educational context for SDA is the classroom in the formal education system. The D2 is normally the standard dialect, and the emphasis is on grammar and vocabulary, rather than pronunciation. The learners are initially children who come to school speaking an unstandardized dialect markedly different from this standard—usually in one of the following categories:

1. Regional dialects: for example, D1 Swabian, D2 standard (or High) German (Ammon, 1989);
2. Colloquial varieties in diglossia settings: for example, D1 Greek Cypriot dialect, D2 standard Modern Greek (Yiakoumetti, 2006);
3. Ethnic dialects: for example, D1 African American English, D2 standard American English (see Rickford, Sweetland, & Rickford, 2004).

Other common situations may involve older students. These include “heritage language learning” settings: for example, speakers of Chicano or Puerto Rican Spanish in the USA learning standard Spanish (Fairclough, 2005). There are also cases of immigrants who speak varieties of World Englishes, for example, speakers of Philippine English learning standard American English (Tayao, 2006).

Finally, another classroom situation can be considered as entailing SDA, although the varieties involved are not normally considered to be dialects of the same language. This is where the D1 is a creole language and the D2 is the standard form of its lexifier (the language which provided the bulk of its vocabulary), which is used in the education system: for example with Hawai’i Creole (D1) and standard American English (D2). While most linguists would say that such creoles and their lexifiers are separate languages, a large proportion of their speakers view them as different varieties of the same language. Classroom SDA, then, occurs for speakers of creoles in countries such as Jamaica and Guyana (Craig, 1999), and for creole-speaking immigrants in countries such as Canada and the USA (Winer, 2006).

Key Issues in Classroom SDA

The most striking aspect of classroom SDA is that it is usually expected to occur without any specific teaching or academic program. D1 speakers are not considered to be language learners, and are not given any special instruction to help them acquire the D2. The reasons for this include the similarity between the first and second dialect (D1 and D2) as opposed

to a first and second language (L1 and L2). The view persists that dialects are simply careless speech or incorrect forms of the standard dialect. In addition, there is the belief that using the students' D1 as a bridge to learning the D2 in the classroom would disadvantage students by exacerbating interference and by wasting valuable time that could be devoted to the standard. Siegel (2006) presents a rebuttal of these views and other unfounded arguments against using the D1 in the classroom.

However, unstandardized dialect- and creole-speaking students are truly disadvantaged in many other ways. First, they have to learn how to read and write in a variety of language that they do not already know (the D2), and learn content in subjects such as mathematics in that variety as well. Second, they may become frustrated by constant correction and not being able to express themselves in the variety they do know, their D1, which is usually denigrated or not considered appropriate for the classroom, or both. Regional and ethnic dialect speakers in mainstream programs and immigrants speaking indigenized varieties and creoles are faced with the additional disadvantage of having to compete with classmates who already speak the D2. Other obstacles include negative attitudes of teachers, who often know very little about their students' D1 and therefore cannot distinguish errors caused by systematic differences between the D1 and the D2 from those caused by carelessness. There are also issues of social identity, as students may be averse to learning and using the D2 because it is seen as closely associated with a different social group. With regard to linguistic factors, students may be unaware of the more subtle linguistic differences between the D1 and the D2.

Pedagogical Approaches

The teaching of standard English as a second dialect approaches of the 1960s and 1970s did attempt to give special instruction in SDA using methodology from foreign-language teaching (FLT) or teaching English to speakers of other languages (TESOL). However, these approaches were abandoned as being ineffective or inappropriate (Siegel, 2003). More recent approaches make use of the students' D1 to help them acquire the D2. The instrumental approach uses the students' D1 as a medium of instruction to teach initial literacy and sometimes content subjects such as mathematics, science, and health. This approach has been implemented in situations where the D1 is clearly distinguished from the D2 and where all students in the classroom are speakers of the D1—for example, in creole-speaking countries such as Haiti and the Seychelles, and communities in Australia and Papua New Guinea.

In the accommodation approach, the D1 is not a medium of instruction or subject of study, but it is accepted to some extent in the classroom, for example, by sometimes allowing students to speak or write in their home varieties, or utilizing students' own interactional patterns and stories for teaching the standard. Literature and music from students' communities may also be accommodated into the curriculum. Unlike the instrumental approach, speakers of unstandardized dialects involved in the accommodation approach can be in a mainstream classroom alongside other students who speak varieties closer to the standard. This approach has been successfully used with speakers of African American English and Hawai'i Creole.

In the awareness approach, the students' D1 is seen as a resource that can be used for learning the standard D2 and for education in general. Teaching programs using this approach have at least two of the following three components. In the accommodation component, students' D1 is accepted in the classroom in various ways, as described above. In the sociolinguistic component, students learn about variation in language and the many different varieties that exist, such as types of dialects and creoles. They also find out about

the sociohistorical processes that lead to a particular variety becoming accepted as the standard. In the contrastive component, students learn about the rule-governed nature and linguistic characteristics of their own varieties and see how they differ from those of the varieties of other students and from the standard. This approach can also be used in classrooms where students have a variety of linguistic backgrounds. Several awareness programs have been evaluated, for example, for speakers of Hawai'i Creole (Afaga & Lai, 1994), the Greek Cypriot dialect (Yiakoumetti, 2006), and African American English (Maddahian & Sandamela, 2000). These show that this approach, like the instrumental and accommodation approaches, leads to greater interest and motivation and higher rates of participation. In addition, they result in higher scores in tests measuring reading, writing, or oral skills in the standard D2 and in some cases to increases in overall academic achievement.

Teaching a Third Language

ULRIKE JESSNER

Introduction

In 1962 Elizabeth Peal and Wallace Lambert published an article on the cognitive advantages of bilingual children in the Montreal area (Peal & Lambert, 1962). Although several critical voices were raised with regard to the research methodology employed in the study, their work motivated a number of scholars to pursue this line of research and, after nearly fifty years of intensive study of the phenomenon of multilingualism, it has become widely known that under certain conditions multilingualism can be cognitively advantageous. A strong focus on multilingualism as a characteristic feature of citizenship has been detected as a recent step in sociopolitical and educational development in the European context. In line with this development, an increasing number of scholars worldwide have shown particular interest in third language acquisition (TLA) (see geographical distribution of authorship in articles in the *International Journal of Multilingualism* since 2004).

Definitions of Multilingualism and Third Language Learning

Multilingualism is still seen as an exception and is equated with multiple monolingualism, that is, it is assumed that somebody can only be called multilingual if s/he knows all of her/his languages on native speaker level. Ever since Grosjean's publication in 1985 on the bilingual as a specific but competent speaker-hearer, more researchers have arrived at a more realistic view of bilingualism. Nowadays scholars, even those with different theoretical backgrounds working in the field, seem to agree that multiple monolingualism has to be considered a very rare phenomenon, if existent at all. In multilingual context, languages are used and acquired in dependence of the need for the multilingual individual, and the languages used on a daily basis complement each other in the multilingual repertoire (Grosjean, 2010). As a further development of Grosjean's ideas and as a reaction to ideas from Chomskyan linguistics, Cook (2003) has developed the concept of multicompetence, which is described as a kind of supersystem distinguishing the monolingual speaker from the L2 user.

The term "multilingualism" has been used for different linguistic phenomena. Whereas for a group of scholars it refers to bilingualism as the most common researched form of multilingualism, others prefer to use it only when more than two languages are involved since for this group it is also important to note differences between second and third language acquisition processes (for an overview of the discipline see Aronin & Hufeisen, 2009).

Languages are acquired in natural and instructed contexts and the two forms often intertwine. In many cases worldwide, English is studied as a third language (Cenoz & Jessner, 2000). This is the case, for instance, in bilingual migrant children such as Turkish children in Austria who get in contact with English as a first foreign language at school. Also in all minority-language contexts, such as the Basque Country or Friesland in Europe, English is learned as a third language, if introduced as the first foreign language. But third

language learning can also take place at school when a second foreign language is taught, for instance French or Spanish in German schools (for more examples of trilingual scenarios see Hufeisen & Jessner, 2009).

Research on Third Language Learning in Instructed Settings

Research on third language learning has been concerned with sociolinguistic, psycholinguistic, and educational aspects of the multiple language learning processes. Sociolinguistic studies investigate multilingual communities, whereas psycholinguistic studies focus on the individual multilingual learner, and educational studies of third language learning concentrate on specific learning contexts and the conditions and products of language learning. The most frequently third languages researched are English, German, and French (for a list of studies see Jessner, 2008).

Psycholinguistic studies have played a major role in L3 research since the formation of the new discipline of TLA was heavily influenced by results stemming from psycholinguistic studies on crosslinguistic influence. In a number of studies it was found that the L2 in the multilingual system fulfills a particular role in the L3 learning process. When L3 learners rely on their prior language knowledge, they tend to fall back on their L2 as a source default and supplier language in the learning process, which has turned out to be governed by factors such as psychotypology, recency, and the foreign language effect (for an overview see De Angelis & Dewaele, 2009). But also linguistic and language learning awareness play a key role in L3 learning models, such as the factor model proposed by Hufeisen (see Hufeisen & Jessner, 2009) and the dynamic model of multilingualism proposed by Herdina and Jessner (2002). Both proposals have turned out influential for L3 teaching.

One of the issues that have turned out to be of concern for all areas of research is language attitudes or attitudes toward languages. The prestige of a language (or a language variant) not only influences a multilingual's willingness to maintain a migrant or minority language in a new environment, but it also exerts influence on the attitudes toward learning further languages (see Lasagabaster & Huguët, 2007, for a large-scale questionnaire study on the attitudes of preservice teachers toward third language learning). Another area of major interest focuses on the age factor. Recently published data have shown that an early start of English as a third language does not necessarily lead to the expected high level of proficiency because of limited input (see Cenoz & Jessner, 2009, for a more detailed discussion).

Multilingual Teaching

As there is ample evidence from TLA research that learning a second language differs from learning a third, implications for the teaching context arise from this knowledge. These mainly concern the development of cross-language approaches to language learning, a common curriculum for all language subjects in an institution, and consequently changes in teacher training toward multilingual teacher training. All in all, a multilingual approach to language teaching needs to be developed (see Hufeisen & Jessner, 2009).

A number of cross-language approaches to language education have been suggested to foster synergy effects and cross-fertilization through cooperation between the languages and the language subjects in a classroom. These suggestions present the results of research on multilingualism and of scholars interested in language awareness. For example, Hawkins already in 1999 referred to language learning as language apprenticeship by emphasizing that the main aspects of language learning concern the process of how to learn to learn a language and to engage in cross-language comparisons with particular reference to the role

of L1 in second language learning (Hawkins, 1999). Cummins (2001) suggested transformative pedagogy using collaborative critical inquiry to develop critical language awareness. Students should be made aware of language forms and uses, and this can be partly done through crosslingual comparison of European languages deriving from Latin and Greek such as cognates and proverbs. An increased focus on multilingual awareness as a core ability of multilingual proficiency (or multicompetence) has been suggested by Jessner (2006) as a prerequisite for multilingual teaching.

In a number of European projects, new approaches to multilingual teaching have been developed. For example, the EuroCom (European Comprehension) project (www.eurocom-frankfurt.de) has concentrated on how to provide European citizens with a solid linguistic basis for understanding each other, at least within their own language family. Such an approach includes optimal inferencing techniques in typologically related languages in order to develop at least receptive skills in the new language and has so far been applied to Romance, German, and Slavic language families. At the center of interest in other projects has been the creation of synergy in language learning by learning and teaching beyond language borders (see Hufeisen & Jessner, 2009, for more details).

The ultimate goal of all these efforts is to arrive at a common curriculum for teaching languages in institutional contexts (Hufeisen & Lutjeharms, 2005). Such an integrated approach to language teaching requires the cooperation of all the language teachers in an institution as well as teacher training that focuses on developing language and language learning awareness among the teachers, students, and teachers as learners, since language learning is a life-time process. Furthermore, such a curriculum should be able to integrate minority or heritage languages, or both, as well as a number of foreign languages which are of interest to the social community, and it should be based on training of all teachers as multilingual teachers (Krumm, 2005).

Outlook

There is no doubt that multilingualism is interpreted as useful. Yet, if we want to guarantee multilingualism for all, not elite multilingualism for some, the application of multicompetence approaches to language proficiency development offers a promising way of how to approach the multifaceted challenges of multilingual teaching. This means that politicians who struggle with the challenges of migrant education have to be informed by multilingualism researchers with a holistic point of view, focusing primarily not on the deficits of multilinguals in the dominant language, but on all the linguistic and cognitive abilities of a multilingual learner. Such a view needs to be called upon for the development of multilingual teaching as well as multilingual assessment methodology in all contexts. Consequently, a reorientation toward multilingual norms is necessary to understand the requirements of successful multilingual education.

Teaching and Learning of Interpreting

CHRISTINE W. L. WILSON

The teaching and learning of interpreting has a short history. Although interpreting has shadowed human activity throughout the ages, the first practitioners of interpreting were people with language skills, but without training in interpreting. As has been observed in more recent times, these “natural” or “lay” interpreters would interpret intuitively; subsequently, knowledge acquired through personal experience might be shared with others beginning to interpret, as master to novice.

With some rare exceptions (see Caminade & Pym, 1998, pp. 280–2), the first examples of formal teaching and learning of interpreting date from the 20th century, born out of the emergence of interpreting as a profession. A number of influences began driving forward the first waves of this evolution. First, changes in international relations, including the establishment of the United Nations (UN) in 1945, and technological developments enabling simultaneous interpreting. Second, the spread of globalization. Third, the growing respect for equality and diversity both between countries (e.g., as encapsulated in the status of the official languages of the member states of the European Union [EU]) and within countries (e.g., as regards the languages of minority communities—including indigenous Deaf communities). The professionalization of interpreting entails a need for both quality interpreting and an increased number of interpreters; it also highlights the fact that it is not sufficient to rely on people who happen to be bilingual or polyglot, but rather there is a need to educate people as interpreters. Following World War II, this realization motivated universities in Europe, Asia, the Americas, Africa, and Oceania to offer courses in interpreting. However, as highlighted by Angelelli, “interpreting entered academia in order to meet a pragmatic need rather than to become an object of study” (see Angelelli, 2004, pp. 8–12).

Whilst there is general consensus within the profession that the initial teaching and learning of interpreting should take place at university level—as for any professional activity—there is some tension between “training” (vocationally motivated and market-driven) and “education” (socially situated learning rooted in theoretical principles). This tension is deep-rooted, since even within the university sector there is a tendency to use the term “training,” remarks Angelelli whilst exploring the consequences of divorcing “training” from research and theory in interpreting education (2006, p. 23). In contrast, those who rely on the services of interpreters often favor vocational routes of training because they want more interpreters, faster. The reality tends to be dictated by financial considerations tempered by legislative and policy requirements, underpinned by considerations of quality.

The teaching of interpreting is often viewed as divided into two distinct fields of activity: conference interpreting (CI) and community or public service interpreting (PSI). However, there is a third field, often referred to as signed language interpreting (SLI), which straddles both fields of activity. These three fields are not in the same phase of professional development (Pöchhacker & Shlesinger, 2002, p. 5).

Teaching Structures

The teaching and learning of interpreting does not conform to a single pattern: rather there exists a spectrum of approaches depending on the country (or region within a country), the languages involved, or the field of interpreting. At one extreme remains the self-taught interpreter, followed by induction and basic training provided by organizations (including public sector and nongovernmental bodies) or interpreting agencies. Then there are short courses offered by training providers (possibly private) which sometimes lead to formal accreditation by a professional body or national authority. A significant proportion of the teaching of interpreting takes place in vocational colleges and, at the other end of the spectrum, degree courses are offered at undergraduate and postgraduate levels in universities. Differences in modes of delivery add further layers of complexity: as well as full-time courses, more flexible options, such as part-time, blended, or distance learning, may be offered.

An enduring challenge in the teaching and learning of interpreting is how to ensure “professional readiness”—how to bridge the divide between training or education and professional practice. It is common for courses to integrate “real world simulations” into teaching, and some institutions incorporate formal work-based experience into their programs. However, different positions are adopted regarding the role of a traineeship: in some cases it is combined with the taught course (prequalification), whereas an alternative model is for students to first complete their taught course and then move onto a professional traineeship (postqualification). In other cases, particularly where no traineeship scheme exists, it is the professional interpreting body or other more experienced members of the profession or in the workplace acting as mentors who help the newly qualified interpreter make the leap from learner to professional.

Indeed, given the constrained scope of any taught provision, as well as the range and evolving nature of interpreting activity, it is important to recognize the vital nature of continuous professional development (CPD) and the role of employers, professional interpreting bodies, and international events (such as workshops at conferences) in facilitating this.

Conference Interpreting

Conference interpreting (CI) can be regarded as the oldest of the three fields, in terms of professionalization and the associated development of formal teaching and learning. This is illustrated by that fact that the first university schools of interpreting, in Moscow, Heidelberg, Geneva, Vienna, and Washington DC (Georgetown University) were founded respectively in 1930, 1933, 1940, 1943, and 1949.

The teaching of CI is almost systematically situated at university level—with a predominance of courses at postgraduate level. A European master’s in conference interpreting has also been developed: offered by 18 partner institutions teaching the same core curriculum. Undergraduate level programs exist; however, the teaching of CI—especially simultaneous in the booth—may be positioned later in study programs when competence in language has been proven.

University CI courses exist in combinations of the world’s most spoken languages—especially the official languages of the UN and the EU—or in languages particularly relevant in the host country. However, when “new” language combinations are required on the international stage, teaching provision may need to be introduced at university level for the first time. International cooperation helps foster developments: for example, the teaching of conference interpreting was formally introduced to China in 1979 thanks to a joint project between the UN and the Chinese government which evolved into the

Graduate School of Translation and Interpretation, Beijing Foreign Studies University, in 1994. Over the years, international bodies (such as the EU and the World Bank) have provided funding to support the development of university interpreting programs, mainly by enabling new countries (e.g., Turkmenistan and Madagascar) to benefit from the expertise of established interpreting schools.

International collaboration amongst universities teaching CI extends to student exchange programs, which allow students to spend a proportion of their studies in partner institutions, and many institutions are members of international networks such as the *Conférence Internationale Permanente d'Instituts Universitaires de Traducteurs et Interprètes (CIUTI)*, the oldest international association of universities with translation and interpretation programs (established in 1960).

The training of teachers of CI is mainly conducted in-house: within universities where new staff learns from more experienced staff. However, reflection on the teaching of interpreting took off in international forums in the 1980s (e.g., the 1986 Trieste conference: *The Theoretical and Practical Aspects of Teaching Conference Interpreting*) (Gran & Dodds, 1989) and professional bodies (e.g., the *Association Internationale des Interprètes de Conférence* or AIIC) and major employers (e.g., EU bodies) have been proactive in facilitating opportunities for the training of trainers. Specific developments, such as the certificate course offered by the University of Geneva (launched in 1996) which has led to the development of a master's in interpreter training, and the master's in translation and interpreting pedagogy offered by Macquarie University, Australia, illustrate the progress which has been made. Nonetheless, the education of teachers of conference interpreting is still regarded as insufficient.

Community or Public Service Interpreting

The teaching and learning of community or public service interpreting (PSI) between spoken language pairs presents a much more fragmented picture with provision situated all along the spectrum of possibilities. The position will primarily be determined by a country's particular circumstances: for example, whether it has several official languages (Canada) or depending on the country's policies regarding migration and multiculturalism. Even in countries with long-established, well-developed provision for certain language pairs (e.g., Australia, or Sweden where the teaching of PSI dates from 1968), basic provision may remain all that is available in language combinations new to the country or involving so-called "rare" or "exotic" languages. As stated by Hale in 2007, "compulsory pre-service training in Community Interpreting is far from being a reality anywhere in the world" (Hale, 2007, p. 166).

When PSI is taught in state institutions, it tends to be situated at vocational college level, rather than university level. Furthermore, courses are often short, part-time, or CPD courses, rather than courses integrated within the national education system. In a study on provision in the United Kingdom, De Pedro (2010, p. 101) "surmised that only one university offers a one-year specialized programme" in PSI. However, worldwide, a number of universities integrate PSI as a specialization within existing interpreting degree programs and there is a growing consensus within the interpreting profession that the teaching and learning of PSI should be provided at university level. This is particularly true as regards certain subdomains such as legal or medical interpreting—a trend which is likely to be further stimulated by legislative changes and the setting of standards, as well as the increasing interest of international professional interpreting bodies, such as AIIC, in PSI, and models provided by country specific bodies such as the National Accreditation Authority for Translators and Interpreters (NAATI), in Australia. Since 1999, CIUTI also accepts as members institutions which only teach PSI.

The teaching of dedicated, university-level courses in the subdomain of legal or court or judiciary interpreting has an established history in some countries, but this is not a general rule. In the USA, for example, against the background of the Court Interpreters Act of 1978, a first certificate course in court interpreting was offered in 1983 (Monterey Institute of International Studies) and the first degree program (currently MA in bilingual legal interpreting Spanish–English) was launched in 1996 (University of Charleston, South Carolina). In addition the National Association of Judiciary Interpreters (NAJIT), founded in 1978, provides active support for education in the sector (Mikkelsen, 1999, p. 7). On the African continent, a BA in court interpreting was launched in 2000 (University of South Africa). In contrast, in Canada, Vancouver Community College offers the only training in court interpreting. In Europe, factors such as the 2010 European directive on the rights to interpretation in criminal proceedings (Council of the European Union, 2010) and the activities of the European Association of Legal Interpreters and Translators (EULITA), founded in 2009, are expected to drive forward the development of courses.

The subdomain of medical or health care and mental health interpreting is served by a wide diversity of courses. A sampling of 33 medical interpreter training programs in the USA (Hablamos Juntos, 2005) found that courses ranged from six hours to twelve months in duration; even university provision varies significantly—short courses, graduate certificates, single modules (see Ertl & Pöllabauer, 2010). This is a common pattern: for example, Monash University (Australia) offers two professional development modules in health interpreting, the second of which focuses on mental health. The master's program in health interpreting and health applied linguistics, at the University of North Texas (launched in 2004), is a rare example of a dedicated degree in this field.

In addition to concentration on certain domains within PSI, university-level provision may remain restricted to the more commonly used languages in a country (e.g., the Spanish/English language pair dominates in the USA). Therefore, despite the movement toward university degrees, there is some evidence of another trend: the introduction of qualifications or recognition at a level lower than that agreed to be the appropriate minimum standard. In the United Kingdom, for example, the National Occupational Standards in Interpreting (NOSI) had set this minimum at level 4 (equivalent to final year of an undergraduate degree). In 2010, NOSI trainee interpreter units (at level 3) were introduced. This is a development driven mainly by the needs of PSI and market pressure, but also motivated by considerations of quality in addressing the difficulty some new interpreters (often already providing interpreting services in rarer languages) have in obtaining any professional qualifications (CILT, 2006). Other countries adopt different nomenclature: for example, language aide and recognized, paraprofessional, professional, conference, and conference (senior) interpreter (NAATI, Australia).

Given the number of language combinations required in the PSI field in some countries (often over 100) and limited resources, innovative approaches for delivering PSI teaching in universities have emerged which include courses built around nonlanguage specific core provision, taught in a single language (see Slayter, 2006); flexible, distance or blended learning approaches, including online provision (Skaaden & Wattne, 2009); adult learning; and collaboration between universities in different countries.

Interest in the teaching and learning of PSI has been growing since the first of the series of Critical Link conferences focusing on community interpreting (in Canada, in 1995) and the first Conference of the European Babelea Association for Community Interpreting (in Vienna, in 1999). However, training of the trainers in this field has often not developed beyond courses introducing a particular curriculum (see Furmanek, 2010), with rare exceptions such as the MA in teaching interpreting in the USA (launched 2004), billed as “the only one in the northern hemisphere to focus on public service interpreting didactics” (Wake Forest University).

Sign Language

The history of the recognition and status of a sign language in its native country is likely to impact on where the teaching and learning of sign(ed)/spoken language interpreting is situated. Consequently, in the USA, where sign language was not forced “underground” as in some other countries, structures for teaching and learning American sign language (ASL)/English interpreting became the focus of attention in the 1960s (e.g., when it was agreed, in 1964, that a workshop for interpreter educators should be held to develop a curriculum for interpreter training programs) and the Conference for Interpreter Trainers (CIT) was established in the USA in 1979 (Ball, 2009, p. xi). In Europe, in Sweden, sign language interpreter training began in 1968, the same year as community interpreting (Hein, 2009, p. 125), but in a number of countries worldwide, where acceptance of the indigenous sign language is still emerging, formal teaching of SLI is still to be established. In India, for example, where an association of sign language interpreters was founded in 2007, interpreter training is emerging, but remains minimal (Rao, 2007). The World Association of Sign Language Interpreters (WASLI) is very active in promoting the teaching and learning of interpreting worldwide.

The teaching of SLI is often situated in colleges and is primarily vocational in nature. However, university courses (undergraduate and postgraduate degrees) exist. Initially, many courses were housed within social science or Deaf studies departments, but sign languages have become integrated into a number of university schools of translation and interpreting as one of the languages in their portfolio—sometimes as separate programs (e.g., Macquarie University, Australia), but in some cases (e.g., University of Graz, Austria) sharing the same curriculum as spoken language students. There is also international collaboration between universities: for example, a joint European Master’s in Sign Language Interpreting (EUMASLI) developed by universities in Finland, Germany, and Scotland. In some respects, SLI leads the field, for example, a bachelor’s degree specializing in medical interpreting exists for American Sign Language/English (Rochester Institute of Technology/National Technical Institute for the Deaf). WASLI has also published guidelines for interpreter education (Russell & Locker-McKee, 2009) to assist countries developing provision.

In the SLI field, there are also opportunities for the training of the trainers of interpreters; the first of the interpreter trainers’ workshops organized in association with the European Forum of Sign Language Interpreters (EFSLI) conference took place in 1999, in Madrid, and Macquarie University’s MA in translation and interpreting pedagogy is also open to teachers of sign language. In the USA, a study conducted into the domains and competencies required for teaching interpreting (Winston, 2005) fed into a sign language-specific master’s in interpreter pedagogy (Northeastern University).

Teaching Programs

There is broad agreement regarding the skills required in an interpreter: therefore, general agreement regarding the curriculum of a teaching program. This is evidenced in standards and codes of practice which are often the result of collaboration amongst interpreting practitioners, teachers of interpreting, professional bodies, and service users. However, the balance between the component elements within taught programs varies (see Swabey, 1992, 2002; Gile, 1995; Hertog, 2001; Sawyer, 2004; Angelelli, 2006; Napier, 2006; McDermid, 2009; Ertl & Pöllabauer, 2010).

Interpreting students are expected to develop an excellent level of competence in all their working languages, good knowledge of the cultures related to their working languages and of the professional cultures of the domains in which they work, to understand how communication works, to have cross-cultural competence and good interpersonal skills,

and to be able to manage ethical issues. They also need “translation” skills—to be able to transfer “meaning.” Interpreters need memory skills, voice production and presentation skills, and to be able to prepare for interpreting assignments (to research a topic and build glossaries) and use technology in supporting their work. Angelelli defines the development requirements for health-care interpreting according to six areas: cognitive processing, interpersonal, linguistics, professional, setting-specific, and sociocultural which she then unpacks in more detail (Angelelli, 2006). Cognitive processing development, for example, would include active listening and split-attention; interpersonal development, the concept of role, visibility, and neutrality; and linguistic development, switching between registers, and so forth.

The range of interpreting specific skills students are expected to master may include different modes: such as consecutive (supported by note taking) and simultaneous (which may include *chuchotage*—whispered interpreting—and sight translation). The list may include liaison interpreting and remote interpreting (by telephone or video-conferencing). Interpreters will be expected to function as part of an interpreting team, and perhaps in a relay interpreting situation.

As well as acquiring a range of competencies and skills—particularly in recent years with the shift in focus toward student-centered learning—it is considered important that learners become “reflective practitioners” and courses seek to develop their ability to reflect on their own and their peers’ performance.

This is not an exhaustive list, but illustrates the extensive needs of the interpreting profession and the challenge of addressing the full range of requirements in any teaching program. Therefore, the aim of most courses is to provide a solid foundation in the core skills and the strategies which will enable learners to build on this base and adapt to meet professional challenges.

There remain a number of substantive differences between teaching programs: some concentrate on developing learners’ language skills in parallel with interpreting skills (often in undergraduate level courses), whereas others require learners to have acquired a high level of proficiency in their working languages before learning interpreting (common at postgraduate level). In some institutions learners study translation in parallel with interpreting, but in others interpreting is studied in isolation—or after completing studies in translation.

There are different traditions regarding the number of languages studied and the direction of interpreting: for example, SLI students will be taught to work into sign language—their second or third (B or C) language—even for international conference settings. This would be unusual—except perhaps in local markets—in the case of many spoken languages.

The profile of courses also varies as they respond to the key needs of different interpreting fields. For example, liaison interpreting, *chuchotage*, and sight translation are considered core requirements in any PSI course, but may have less weighting in a CI course with its ultimate aim of preparing interpreters to work simultaneously in the booth. Conversely, the simultaneous mode is used more frequently in PSI settings (e.g., educational or faith related settings in the USA), particularly as PSI interpreters’ skill levels increase, and is the main mode used by sign language interpreters.

At the stage of initial training, except for basic PSI courses, it is unusual for courses to concentrate on preparing students to work in specific sectors, such as the media, medical, or legal domains. Specialization in interpreting is mainly offered postqualification by professional interpreting bodies and others providing CPD.

Traineeships, however, play a key role in teaching and learning interpreting and may be described as a practicum, apprenticeship, or an internship. A practicum usually takes the form of a period of work-based experience—perhaps linked with a study project—to be completed before entering the final year, as a significant part of the final year or following

the final year's taught elements as a requirement for obtaining the award. The use of the "apprenticeship" label (more usually linked with a trade) and the "internship" label (more usually linked with a profession) is a reminder of the training/education tension. The former tends to be used when the work experience and taught elements run concurrently throughout the program. The latter (whether pre- or postqualification) tends to involve a period of "hands on" experience in the professional role (albeit supervised), but the distinction between internship and practicum may be blurred. It is becoming increasingly rare for an interpreting course (especially in the PSI and SLI fields) not to include a traineeship component.

The Teaching/Learning Triad

Learners

A recurring pattern is that the first interpreters come from a background where, due to parentage or personal circumstances, they have grown up mastering the languages required—even fulfilling the role of family interpreter. As most Deaf parents have hearing children, this is particularly striking in Deaf communities, and many interpreters working in the PSI field also come from the minority-language communities.

The second wave of learners often emerges from professions closely associated with the need for interpreting: from diplomatic backgrounds, from social services, or the voluntary sectors.

As the fields of interpreting professionalize, they attract wider attention and, for many students, interpreting becomes the target career on completing college or university. Their ultimate aim is often to work as a staff interpreter, but circumstances—including market demands for certain languages—may dictate that they will work freelance, perhaps in both local and international markets, perhaps offering the full range of interpreting services across conference and public service fields, and perhaps only able to make a living wage if interpreting is combined with other employment. Such considerations inevitably impact on the overall design and resources invested in a taught program, as well as on the demand and competition for learning opportunities.

Where selection onto interpreting courses is permitted within the education system, excellent command of the working languages is often one of the main selection criteria. However, excellence in language does not guarantee excellence in interpreting; conversely, initial weaknesses in language proficiency do not preclude a student developing into an excellent interpreter. Therefore, there has been much debate over how to evaluate interpreting potential and a number of schemes for aptitude testing have been developed (Pöschhacker, 2004, pp. 181–2), although their accuracy remains contentious.

Teachers

The question of whether interpreters should be taught by "practitioners" or "academics" continues to resonate within the body of teachers of interpreting. Nonetheless, it is generally agreed that interpreters should be taught by people with experience of interpreting as practitioners, with knowledge and understanding of pedagogy, of the underlying theoretical principles, and of recent research (see Furmanek, 2010). If these attributes cannot be combined in individuals, a team teaching approach may be successfully adopted. As interpreting fields professionalize, more practitioners conduct research and become members of academic staff which helps dissolve the divisions between theory and practice. There is also growing dialogue and collaboration across fields that are fading the boundaries between CI, SLI, and PSI.

Service Users

A recent focus (particularly in PSI and SLI) is on the role of members of service user groups, including other professional bodies, in the teaching of interpreters. Not simply training such personnel to work with interpreters, but rather the interlinked approach (Perez & Wilson, 2011). This means involving members of other professional bodies (police officers, doctors, etc.) more centrally in the teaching of interpreters and in the development of teaching and guided learning resources: an approach which creates a positive spiral. Furmanek specifically discusses the positive spin-offs of students' internships for service users' learning about interpreting (Furmanek, 2004).

Challenges for Teachers and Learners

Interpreting is not a static field of activity, but is in constant evolution. Models change over time depending on the phase of professional development, the focus and findings of research underpinning practice, and shifts in the contextual framework (e.g., understanding of interpreting on the part of user groups together with increased scrutiny of interpreting). The evolution of technology and the downward pressure on costs also impact on what is expected of a professional interpreter. Consequently, from the moment of qualification, an interpreter's professional readiness faces the need for continuous updating. Therefore, the ultimate objective in teaching and learning interpreting is the development of a solid foundation in the core skills together with the tools to continually reflect on one's own practice and review the practice of the profession.

Teaching and Learning of Translation

KELLY WASHBOURNE

Context: Translators, Academia, and the Marketplace

Translators provide products and services, and work with written documents, as distinguished from interpreters, who work as oral language mediators. Although it is less common to work in both fields, except at the community level, many students in translation and interpreting schools pursue a dual-track degree or course of study. It is generally accepted that the required skill sets for translation and interpreting only partially overlap. Traditionally, translators have learned their craft informally: through on-the-job training or in unstructured apprenticeships. Many translators today still learn by working in the language services market, though an array of program options within academia have opened in the last decades, commonly at the undergraduate (first-cycle) and master's (second-cycle) levels. Graduate or undergraduate certificate programs are another option, and are generally shorter than degree programs. The foundational degree is generally accepted to be the master's, whereas the bachelor's is seen as preparatory. PhD programs (third-cycle) in translation tend to be designed to train not translators but rather scholars of translation, usually in the academic discipline of translation studies. Qualified translation graduates find work as language policy consultants, translation tool vendor representatives, project managers, terminologists, acquisitions editors, literary translators, and translator trainers. Translators are employed in a variety of industries: schools and universities; major newspapers; multinational companies; health care and social assistance, especially hospitals; and other areas of government, such as federal, state, and local courts, or international organizations. Translation agencies (bureaus) also outsource much of their work to translation vendors. Publishing companies are employers of translators, usually through a work-for-hire contract; this type of translation is sometimes known as *editorial translation*. An increasing percentage of translators are self-employed, and thus today's students work toward mastery in more than languages—the mandate for a strong foundation in entrepreneurship exists, as in-house opportunities are growing steadily fewer. Many translators rely on other sources of income to supplement earnings, such as teaching or language consultancy. Most well-developed translation programs around the world offer some form of business of translation course in which such related professionalizing issues of self-marketing, standards and payment practices, and bidding for work are addressed.

Although ethics is a growing area of research within translation studies, it is rare to find courses centered on ethics; usually this important aspect of becoming a translator is incorporated, and not always systematically, into a theory or principles course at the introductory level. To break into the language industry, many inexperienced translators do pro bono humanitarian translation, social services translation, or other work that commonly undergoes close revision by a reviewer or editor. The freelancer's best credential at present, apart from or in addition to a related academic degree or degrees, is to become certified in his or her language combination(s) through such organizations as the American Translators Association in the United States, which also has a mentorship program, and to meet continuing education requirements to keep the qualification current. There are, moreover, many regional, national, and international conferences focusing on translation,

many of which welcome student participation or are open only to students. Online and print journals that feature translation pedagogy research number perhaps in the hundreds, and include, to name only a few, *Translation and Interpreting Studies*, *Translation and Interpreting*, the *Interpreter and Translator Trainer*, *JoSTrans: The Journal of Specialized Translation*, *Current Trends in Translation Teaching and Learning*, and *Chinese Translators Journal*. It may be said, then, that the teaching and learning of translation extend well beyond the classroom.

Training and Education

The term *translator training* is preferred in environments in which industry drives many of the goals, text types, and methods of instruction, in which a vocationalized curriculum lends itself well to measurable learning outcomes, and in which concern centers on actual stakeholders. *Translator education*, by contrast, emphasizes theoretical models, actively promotes and evolves through interdisciplinarity, and privileges the learner's all-around development. These two approaches tend not to be absolute, mutually exclusive, or even clearly defined as such within given programs or in the discipline. Translation faculty rosters are sometimes broadly characterized by an analogous divide: between, on the one hand, practitioners who teach and, on the other, part-time translators—or even non-translators—whose focus is on academic research in translation studies or translation informatics. Qualifications for entry into translator training and education programs vary: Many students enter programs while still in the language acquisition stage, despite some claims that translation competence depends on language mastery. Other student translators may be sworn translators in their home countries, or have experience working as a freelancer or in an in-house (staff) position, the two primary employment options for qualified translators. Just as translators must requalify for each job they are assigned, or have earned the good faith of a translation commissioner, trainees or students must learn to acquire strong subject area proficiency in at least one area in order to compete professionally. They often require on-the-job training in addition to their pre-professional degrees. Some international organizations such as the United Nations, and companies such as SDL, offer internships. Usually the eligible applicant's area of study must be in linguistics, modern languages, or translation. Untrained bilinguals, occupying the “gray market” shadows of industry, and translating without knowledge of best practices and principles of the field, can prove to be a costly, short-sighted investment for all concerned, as a poor translation can damage a brand, company, or professional relationship, and undermine pricing structures and the status of the translation field, which, due to its relative incipency, still incites debates over whether it is a profession or an occupation. Formal translation education, which has made quantum progress since its postwar infancy in the 1950s, alleviates some of the burden of sustaining a largely unregulated industry.

Technology

The teaching and learning of translation are undergoing a technological revolution. Consequently, industry is driving the need for functional ability with *translation tools* and especially their underlying processes, terminology management, and value-added skills such as revising, editing, proofreading, and desktop publishing (DTP). Computer-aided (or computer-assisted) translation tools (CAT tools), also known as translation environment tools (TEnts), include databases for harmonizing terminology and project management, as well as for allowing the user to leverage segments of previously translated text and other content so they can be recycled as needed, commonly known as *translation memory programs* (TM). Another subclass of machine translation (MT) is machine-assisted human

translation (MAHT), which holds out enticing possibilities for the translation pedagogue. Translation schools and programs are catching up with these new realities and demands. Career prospects are growing apace in software internationalization and Web page localization. These areas, which are now requiring course development at both the graduate (postgraduate) and undergraduate levels, consist of tailoring or making products, text, or images acceptable to target-country market norms, and call for considerable engineering and testing work. Multimedia or audiovisual translation, particularly in countries that import and adapt English-language media production, are well represented in graduate seminars throughout Europe, as are other topics from language engineering, such as terminology, and linguistic corpora and their use in translation and empirical translation research. Pioneering use of corpora in translator training has been made in Ireland, England, and Italy, in particular.

Specialized Translation

Specialized translation has its unique problems and pedagogical challenges, not least of which is the problem of terminology, and the perhaps greater, related, problem of conceptual difficulty for the nonspecialist. Kelly and Martin (2009, p. 295) identify the trend of placing specialized translation at the end of the curriculum, suggesting it is more complex. While specialized translation usually demands more documental work for the translator, some argue that general translation in translator training environments is in some ways equally difficult, in that multiple fields must be contended with, and the repetition of concepts and terms is less, hence mastery must happen more quickly. At all events, there is considerable consensus that overspecialization too early in one's academic career runs counter to the trends of the globalized economy, which relies on technologies that quickly can fall out of demand or become obsolete. The best transferable skill in this connection is specialized writing. Many translation programs require a business writing or technical writing component in response to the growing demands that translators become proficient in writing technical and business documentation, as the gap between job descriptions of tech writer and translator becomes more indistinct.

Literary translation, while not a highly remunerative activity, is nevertheless an important area of the field, and is almost universally taught. Literary translation is distinguished from "nonliterary translation," or the perhaps now-preferable term, *pragmatic translation*. Courses in literary translation, both practical and theoretical, often explore such translational phenomena as multiple valid renderings, the problem of a translation's dual authorship, connotation, retranslation, power and patronage, censorship, gender, the status of the translator, the reader's expectations of transparency, translator constraints, and intratextuality and intertextuality. The transferable skills from this *domain*, or translation subject area, lend themselves well to such in-demand translation modalities as "transcreation," a portmanteau used in multicultural marketing to suggest the reconceptualization, cultural adaptation, or creative reworking of the source text—a brand or an ad, for example. This emerging practice is a boon to translation teachers, who can design tasks built around the need for students to negotiate pragmatic, cultural, semiotic, and other dimensions of signification and reception beyond literality. Literary translation has become a part of many creative writing MFA degree programs, and courses in stylistics in particular commonly form part of the literary translator's education, for example at the University of East Anglia (United Kingdom), as do professional scenarios such as editing a journal of literary translation. The *translation of sacred texts* is a domain related to literary translation, and engages many of the same issues, including polysemy, canonicity, and the instability of so-called source texts. Sacred texts in most secular institution classroom contexts are

studied and theorized—compared, historicized, problematized—more than they are translated or retranslated.

Institutional Affiliation

Given the complexities of training and educating translators, and the changing realities in which translators work, controversies about where to house translator training programs do not show signs of abating. As translation professionalizes, one area of contention relates to the debatable claim that the traditional home of translation—modern language departments—often cannot produce faculty possessed of the technological and text-typological competence needed to produce pre-professional learners for industry, as many of these faculty come from liberal arts backgrounds. Compounding this tension are the growing pains associated with the expanding mission of many such humanities departments from linguistics, literature, and culture to a vision that embraces language “for the professions,” outreach, and experiential learning. Some scholars hold that translation should be taught from independent institutes, while others seek to continue to accommodate translation in traditional modern language departments; the latter becomes more untenable as translation becomes less linked with mere bilingualism and is recognized as a highly skilled profession. Translation as a tool to support language learning in language acquisition environments still attracts support, though the practice has fallen into disrepute, at least among many translation theorists. In sum, it is still somewhat rare to find translation housed comfortably in academia, and variables are many and ever-changing: Even the configuration of faculty expertise affects every aspect of translator learning, from what language combinations are offered to the classroom methodologies used.

Directionality

The issue of working into or out of one’s mother tongue (a term that many theorists are now questioning or rejecting) is known as *directionality*. Directionality is a productive, ongoing debate, when not beset by arguments from convenience. Translators in the field work predominantly into the L1, one’s native or “A” language, though there are many exceptions, especially where texts can undergo extensive revision, in cases of team translation, when scarcity of qualified L1 translators make this practice a necessity, or when the document is for “information only.” In *pedagogical translation* (Beeby Lonsdale, 1996, p. 13), or translation for the purposes of improving linguistic skills, translation into a non-mother tongue (L2, or “B” language) is often termed *indirect translation*, and is widely accepted, usually with the tacit understanding that it involves gaining insight into working into one’s adopted language, but is not vocational training for working into the L2. Study abroad is not an absolute requirement in most programs, though translation success unequivocally correlates with a strong and current command of the B language of one’s combination, and particularly the linguistic and extralinguistic knowledge (subject and world knowledge) of the domain area(s) in question.

Models of Translator Training

Typically courses in translation are *language-specific*—“workshop” or practical courses—or *non-language-specific*—theory and craft courses. The role of theory in translator curricula is among the most debated questions in the field; much of the resistance to theory comes from practitioners or students who understand it to be an arcane tangent rather than a

structured body of concepts derived from practice and with real bearing on translations. Also, instructors' overreliance on the literary in canonizing and exemplifying translation theory often hampers theory's wider acceptance in the classroom.

Learning translation today involves focus on the *translation process* as well as the *translation product*. The former has been given impetus in recent decades from data-driven research findings in the cognitive, descriptive, and empirical models of learning: Think-aloud protocols (TAPs) can provide insight into learner decision paths; "learner corpora" reveal patterns of errors and can give valuable predictive information about problem areas; and eye-tracking can aid in discovering the learner's novice behaviors (for example, their overuse of extrinsic resources and underuse of inferencing; or their reliance on smaller translation units, or segments). The processes a translator undergoes place the translator as an actual mediating presence, a decision maker. One timeworn approach to translation—before the 1980s and in many cases still used today—focused exclusively on the source and target texts, with little or no recognition of the translator's agency. Theorists have come to consider the translator as a whole person, a social agent in a nexus of relationships both affective and interpersonal. Studying how translators learn and think, rather than simply how texts work, is a key development in the field. This concern for the learner as well as the learning, typified by learning theory's *process objectives*, which acknowledge the social, political, cultural, and psychological needs of the learner over and above performance (Richards, 2001, pp. 133–4), has gained adherents in recent years among translation teacher-scholars.

Traditional translation practica often assumed translation occurs "in a vacuum," that is, without any sense of how the text would operate in the target system; instructors would model the "correct" translation and measure success in accordance with the student's degree of deviation from it. In the model widely favored today, students, individually or in role-playing teams, are assigned partial-task or whole-task translations that are usually authentic or semi-authentic: actual translation assignments or pedagogically modified versions of them. A *translation brief*, or commission, is provided. Students are challenged to respect the situationality of the texts from and into which they are translating—that is, to use functionalist considerations of how the text will be used, by whom, and any transculturations, changes of register, or additions that the translator may need to, or choose to, perform in response. The functionalist approach—anchored by this application of *skopos*, or function—has been highly influential (see, for example, Nord, 1997, or Kussmaul, 1995). Translation strategies—at both the microtextual and macrotextual levels—figure prominently in these negotiations.

Myriad task and activity types form part of the practical translation sessions, and may include a term project involving a whole workflow: price quote, project term bank, revision, and layout (Reinke, 2005, p. 12, following Nord, 1996); translations in pairs; "gisting" or summary translation; resolution of specific documentation or research problems; contrastive macrotextual analysis of text type conventions between languages; "common pitfalls" and other awareness-raising discussions; "round robin" group edits or translations; information-gap tasks; or role-play enactments of different communicative situations. The learning process in translation practica stresses procedural knowledge, knowing *how* rather than *what*, and conditional knowledge, knowing *when* to apply it. Students unlearn facile received knowledge of "equivalence"—a concept that has fallen under attack as *passé* under the new conceptions of a translation not as a mirror image of the source, but as a rewriting for new purposes. The concept of "fidelity," consequently, is outmoded in favor of *adequacy* to the brief, or in short, of conformity to job specifications. Translator training, then, has evolved beyond contrastive linguistics and discussions of "loss" and "gain." *Competence models* for translation trainees too have grown in complexity, and in most cases include intercultural, interpersonal, and interlinguistic dimensions. One nuanced model,

the EU Tuning Project, identifies *instrumental*, *interpersonal*, and *systemic* competences (Kelly, 2005, p. 35). These include the process-related features of translation that bear not only on abilities but also on translator *qualities* that, although not always objectively measurable, are consistent with good practice (e.g., teamwork, adaptability, commitment).

The full implications of the competences expected of recent graduates have yet to be exploited in curriculum and task design. There is a need for more synthesizing, evaluative tasks that are demanding cognitively and metacognitively, such as updating and verifying glossaries; producing style guides; vetting translators; critiquing field testing practices such as back-translation; devising an assessment standardization; identifying and maximizing different kinds of translational reading, including the active reading needed for parallel text evaluation or intratextual coherence markers; or bringing text-linguistic and discourse analysis insights to bear on actual translations. Curricular design still needs to account more creatively for distance learning and other forms of remote course delivery; interactive, hypertextualized “translation simulators” and scaffolded translations can be built to provide research and drafting support; different trainee learning styles can be empirically defined and accommodated; editing can be brought more formally into the standard skills taught; differences between expert and novice behavior can be introduced into the trainees’ awareness as a diagnostic tool; and ultimately, more “training the trainer” courses can be devised to complement peer learning at conferences. Vibrant, ongoing dialogues and interconnections formed between theory, empirical research, and pedagogical applications are enriching the field for the future in ways barely glimpsed today.

Teaching and learning translation are interdisciplinary in part, perhaps, by the nature of the field, but perhaps too because they are still in their infancy, and derive much from tangential fields; as translation in academia grows, its pedagogy will in turn drive developments on its margins.

Teaching Business English

ZUOCHENG ZHANG

Teaching business English is an important growth area in English-language teaching. It involves understanding three key facets: business, business English, and teaching business English. These aspects will be dealt with in turn below.

Business can be understood narrowly as commercial transactions (Zorn & Simpson, 2009). Broadly, it refers to a wide range of “economic, public, and social activities such as trade, management, finance, marketing, tourism, journalism, and law” (Chen & Wang, 2009, p. 5) or “a range of contexts in which members of various kinds of organisations interact to achieve business, organisational or relationship goals” (Zorn & Simpson, 2009, p. 32). As these understandings specify the wide range of business contexts in which English can be used, they may help in pinning down the scope of business English and the teaching of business English.

Business English (BE) is recognized as an important branch of English for specific purposes (ESP) (Ellis & Johnson, 1994; Dudley-Evans & St John, 1998). Another perspective on business English is that of business discourse. Business discourse is an umbrella term that covers a wide range of research involving the ways people in business use talk and writing to get their work done and to achieve their goals (Bargiela-Chiappini, 2009). While the perspective of ESP offers an operating framework for teaching business English, the business discourse view sheds light on the target situations learners of business English are prepared to function in. These perspectives contribute to defining business English as the teaching of the system of strategic communication in international business in which participants adopt or adapt business conventions and procedures and make selective use of lexicogrammatical resources of English as well as visual and audio semiotic resources to achieve their communicative goals (Zhang, 2007).

While teaching business English shares the principles of ESP, it requires more of the analysis of learner needs, the subject matter, the teacher, and the teaching methodology, each of which will be discussed in detail respectively.

Learners of business English fall into two general types: pre-experience learners and work-experienced learners (Dudley-Evans & St John, 1998). Work-experienced learners are familiar with business operations. They attend business English classes to learn how to conduct familiar business activities in English. As they are usually under time pressure, with certain hours of the working days allocated to training, they tend to have clear objectives to meet for the time frame. Pre-experience learners are usually at an academic institution or a vocational school with no time pressure to meet specific objectives. What they need includes knowledge and skills for their target situations. Lying in between are low-experience learners (Ellis & Johnson, 1994). These learners are usually junior company members or people who are moving jobs. They are learning both about their new job and the language for doing the job. Quite recently there has emerged a special type of pre-experience learner, notably the students of business communication studies in Radboud University Nijmegen in the Netherlands and the business English majors in the University of International Business and Economics in China. These learners are enrolled in faculties of arts or languages, but their curriculum content shifts from the traditional focus on language and literature to international business communication. Take the business English

majors in China, for example. They attend the four-year business English program and will earn a bachelor's degree upon successful completion of the program. In addition to learning business practice and business discourse, they take compulsory courses in business-related disciplines such as economics, management, and international business law (Chen & Wang, 2009).

The subject matter for these various types of learners is specifiable and specific. One of the tenets of ESP is that priority is given to learners whose needs determine what to teach and how to teach (Hutchinson & Waters, 1987). Learner needs are usually described with reference to their purposes of learning, target performance situations, starting level, and target level (Ellis & Johnson, 1994). The descriptions have been evolving, reflecting the changing understanding of the nature of business English. Since the 1960s, the teaching of business English has undergone several stages of change, from the teaching of specialist vocabulary to speaking, listening, reading, and writing skills in business contexts, to notions and functions, to business communication skills such as presentations, meetings, and negotiating (Ellis & Johnson, 1994). As research in business discourse continuously exposes practices and language use that characterize business professionals, the curriculum content for business English students incorporates more and more knowledge of business. For example, the curriculum for business English majors in China draws on Bhatia's (2002, 2004) theoretical framework of professional expertise described in terms of disciplinary knowledge, professional practice, and discursive competence (Zhang, 2008). There are courses in disciplinary knowledge, like micro- and macroeconomics, marketing, finance, and fundamentals of business law. The courses that represent professional practice include international business, professional etiquette, and business ethics. Courses in business discourse involve a range of genres and activities that students expect to handle in their study of the disciplinary knowledge and professional practice.

The teacher of business English should be subject-informed. It was once widely believed that ESP teachers were language specialists and it was not necessary to have subject expertise (Hutchinson & Waters, 1987; Ellis & Johnson, 1994). This assumption was accepted by many at a time when ESP was promoted by language teachers who generally received training in language and language teaching rather than business subjects. Yet when pre-experience learners, especially business English majors, are involved, a teacher with no idea of the subject matter will find it much more difficult to survive in the business English classroom. On their list of the areas of knowledge and understanding for teachers of business English, Dudley-Evans and St John (1998) put "some knowledge of management theories and practice" (p. 61).

Since business English has the goal of preparing learners for expert performance in their target professional situations, teaching methodology is best described as eclectic and learner-oriented—that is, ready to adopt whatever methods will ensure learning. In the case of job-experienced learners, the teacher is likely to play the role of a language consultant (Dudley-Evans & St John, 1998). The "deep-end strategy" (p. 190) may be effective. According to this teaching strategy, learners may be set a task to perform using their existing English competence. Their performance reflects their personal and professional approach to the task at hand. For pre-experience learners, in particular business English majors, teaching is informed by subject-specific methodologies such as role play (Ellis & Johnson, 1994) and case study (Almagro Esteban & Pérez Cañado, 2004; Zhang, 2008), as these methods help learners both to take in knowledge and to gain hands-on experience of business operations and the language in use in these practices.

A number of issues can be identified in teaching business English at the present time. Teaching business English understandably aims at bridging the gap between the classroom and the workplace (Bhatia, 2004). It thus requires a sound description of the target situation. Although research in ESP and business discourse has been accumulating, partly thanks to

research partnership between academics and business professionals (Cheng & Mok, 2008), a systematic description of the English in use in international business contexts is still needed (Seidlhofer, 2004; Nickerson, 2005; Piekkari, 2009). The research findings available also need to be translated into teaching materials (Nickerson, 2005; Kankaanranta & Louhiala-Salminen, 2010).

The social theory of learning with its emphasis on practice (Wenger, 1998) has had a tremendous impact on business English education. Learning business English is more about picking up a practice and taking on a professional identity. This opens up new understandings of the goals of business English education. It also has implications for the process of teaching business English. For example, learning can be viewed as a process where learners become legitimate participants being socialized into the target community of practice under the guidance of their teachers, ideally as expert participants who provide them with role models. This view puts the learner firmly at the center of learning. It has the potential for transforming the teacher–student relationship. Moreover, authenticity and specificity (Dudley-Evans & St John, 1998) will be crucial in materials and task design.

As critical studies of business discourse reveal the ways inequality in race, gender, and power is embedded, naturalized, or neutralized in business discourse (Mullany, 2009; Parker & Grimes, 2009), these findings are likely to prompt teachers and students of business English to be critically aware of the operations of business discourse. The “accommodationist” approach to teaching, that is, being uncritical about and restricted to helping learners to cope with their target performance situations (Dudley-Evans & St John, 1998, p. 231), will receive increasingly critical attention. This development calls into question the ideology underpinning ESP education and the teaching of business English, and may indicate a shift away from the focus on meeting the practical needs of students and the workplace to recognizing the urgency of preparing students for addressing social inequality and injustices and participating in increasingly globalized and multicultural societies (Richards, 2001).

Teaching Culture and Intercultural Competence

CLAIRE KRAMSCH

What Is Culture?

Despite the numerous definitions offered by applied linguists, many language teachers still don't know how to define culture nor how to teach it. Many are not convinced that it is the role of the language teacher to teach something that is better taught by anthropologists, sociologists, literary critics, or historians. Which aspects of culture should be taught in a language class: facts of geography and history, national symbols, small cultures or ways of life, myths, and ideologies? Which kinds of culture: national, regional, professional culture; high culture or popular culture? And whose culture should be taught: the culture of a target country or the hybrid culture of multilingual individuals who straddle various national cultures?

These questions affect different language teachers differently, depending on the needs and purposes of their students. Where foreign languages are learned for professional opportunity, physical survival, intelligence gathering purposes, or even for mere philological or linguistic interest, culture may be perceived as a less important component of language study. By contrast, where they are learned for intercultural understanding, for social survival in an immigration context, for reconnecting with one's linguistic and cultural heritage, or for general humanistic purposes, culture becomes central to the language learning enterprise. Which aspects of culture and whose culture will be worth teaching will also depend on the symbolic value of the language taught and on the educational priorities of the educational institution.

There are roughly two different ways of looking at culture in language teaching, depending on one's disciplinary and political orientation, and on whose interests are being served: modernist and postmodernist. These two perspectives on culture coexist today in the theory and practice of language learning and teaching.

Teaching Culture: Modernist Perspectives

Until the 1970s, culture was seen as the literate or humanities component of language study. In the 1970s and 1980s, following the communicative turn in language pedagogy, culture became synonymous with the way of life and everyday behaviors of members of speech communities, bound together by common experiences, memories, and aspirations. In both cases, speech communities were seen as grounded in the nation—the national context in which a national language was spoken by a homogeneous national citizenry.

Big C Culture

As a humanistic concept, culture is the product of a canonical print literacy acquired in school; it is synonymous with a general knowledge of literature and the arts. Also called "big C" culture, it is the hallmark of the cultivated middle class. Because it has been

instrumental in building the nation-state during the 19th century, big C culture has been promoted by the state and its institutions, for example, schools and universities, as national patrimony. It is the culture traditionally taught with standard national languages. Teaching about the history, the institutions, the literature, and the arts of the target country embeds the target language in the reassuring continuity of a national community that gives it meaning and value. National cultures are always bound up with notions of the “good” and “proper” way of life which is why they elicit pride and loyalty. Because they are imbued with moral value, language learners who have grown up with other values find it often difficult to understand foreign cultures on their own terms. They find refuge in cultural stereotypes, or in literary fiction. With the advent of communicative language teaching, the humanistic concept of culture has given way to a more pragmatic concept of culture as way of life (the little c culture, see below). But the prestige of big C culture remains, if only as *lieux de mémoire* in Internet chatrooms named, for example, *Versailles*, *Madison Avenue*, or *Unter den Linden*—cultural icons of symbolic distinction.

Little C Culture

With the focus now on communication and interaction in social contexts, the most relevant concept of culture since the 1980s has been that of “little c” culture, also called “small cultures” (Holliday, 1999) of everyday life. It includes the native speakers’ ways of behaving, eating, talking, dwelling, their customs, their beliefs, and values. Research in the cultural component of language learning has been deeply interested in cross-cultural pragmatics and the sociolinguistic appropriateness of language use in its authentic cultural context. To study the way native speakers use their language for communicative purposes, the convention of “one language = one culture” is maintained and teachers are enjoined to teach rules of sociolinguistic use the same way they teach rules of grammatical usage, that is, through modeling and role playing. Even though everyday cultural practices are as varied as a native speaker’s use of language in everyday life, the focus is on the typical—sometimes stereotypical—behaviors, foods, celebrations, and customs of the dominant group or of that group of native speakers that is the most salient to foreign eyes. Striking in this concept of culture is the maintenance of the focus on national characteristics and the lack of historical depth.

The sociolinguistic concept of culture takes on various forms depending on whether the language taught is a foreign, second, or heritage language. In foreign language (FL) classes taught outside of any direct contact with native speakers, culture is mostly of the practical, tourist kind with instructions on how to get things done in the target country.

FL learners learn about the foreign culture as an exotic curiosity; they try to adapt to it or temporarily adopt it as their own when they travel to the country. In second language (SL) classes taught in the target country or in institutions run by native speakers abroad (e.g., British Council, Goethe Institute, Alliance Française, Instituto Cervantes, Confucius Center), culture can also take the form of exposure to debates and issues of relevance to native speakers in the target country, or of discussions about living and working conditions for immigrants. In the same manner as children are schooled into becoming proper citizens, so are immigrants acculturated into the *habitus* of nationally defined native speakers; they acquire a national home they can be loyal to and a national identity of which they can be proud. Culture as a process of nurturance and socialization is achieved mainly through schooling in its written, literate tradition (Kramsch, 1998). This notion of culture as nurture is of course never very far from culture as control.

In heritage language (HL) classes taught to native speakers who wish to connect with their ancestral roots, culture is the very *raison d’être* of language teaching. It is not, however, without presenting major difficulties when the heritage community has either lost much of its original everyday culture (e.g., Native American languages), or when its speakers

belong to a community that historically no longer exists (e.g., Western Armenian or Yiddish). The teaching of culture in HL classes is very much linked to identity politics.

Intercultural Competence

The term “intercultural” emerged in the 1980s in the fields of intercultural education and intercultural communication. Both are part of an effort to increase dialogue and cooperation among members of different national cultures within a common European Union or within a global economy (see Jackson, in press). In Europe, the concept of intercultural competence emerged alongside the concept of communicative competence (e.g., Byram, 1997) with a social and political orientation (for excellent surveys, see Risager, 2007). Byram and Zarate (Byram, 1997) identified five *savoirs* or capacities that constitute intercultural competence: *savoirs* (knowledge of self and other, of interaction, individual and societal); *savoir apprendre/faire* (skills to discover, interact, or both); *savoir comprendre* (skills to interpret and relate); *savoir s’engager* (critical cultural awareness, political education); *savoir être* (attitudes: relativizing self, valuing others). Recently some European educators (see, e.g., Hu & Byram, 2008) have used various ways to evaluate intercultural competence, based on the Common European Framework of Reference and on Milton Bennett’s model of intercultural relativity (Bennett, Bennett, & Allen, 2003).

In the United States the development of intercultural competence is at the core of genre-based literacy curricula (Byrnes, 2002) or online telecollaboration (Ware & Kramsch, 2005) at the college level. It has been recently promoted in foreign-language departments as an organizing principle of the curriculum (Schulz & Tschirner, 2008). In all these cases, culture is a modernist notion tied to the characteristics of native members of a national community who speak the national language and share in its national culture. This modernist definition of culture has been challenged by a lingua franca like English that knows no national boundaries, and by global social actors who contest the supremacy of the native speaker as well as the notion of neatly bounded speech communities (see next section). The notion of the third culture kid (TCK) (Dewaele, 2009), that captures the transnational identities of today’s multilingual, hybrid, mobile youth, can be seen as a late modern phenomenon that has fueled the imagination of postmodernist scholars (see below). Because TCKs have loosened their ties to any particular culture of origin, their trans- or multinational identities have helped researchers understand the postmodern condition of the multilingual individual (for a proposal for a transnational pedagogy, see Risager, 2007).

The concept of intercultural competence has been given a new meaning by those who use computer-mediated communication (CmC) to foster interaction in the L2 between native and non-native speakers (NNS) and among NNS, and to enable them to access and manipulate foreign cultural environments (Kern & Warschauer, 2000). Intercultural competence has been both enhanced and impeded by CmC. On the one hand, the increased use of CmC to develop L2 communicative competence has led to a reorientation of language learning toward conversational fluency, online chatting ability, the negotiation of surface features of speech, and a focus on common experiences in the here-and-now. It has enhanced participation in online communities (e.g., Lam, 2008) and the development of identities liberated from the social constraints of the real world (Baym, 2000, pp. 143–74). On the other hand, the direct access to L2 speakers and the cultural immersion provided by CmC has enhanced the illusion of semiotic immediacy and cultural authenticity that has sometimes led to disappointment if not outright hostility in intercultural encounters (e.g., Ware & Kramsch, 2005). It has not necessarily led to the in-depth exploration of cultural, historical, and ideological differences. In the globalized geopolitical landscape of today, there is a growing interest among applied linguists for more complex, ecological approaches to culture that are postmodernist in outlook.

Teaching Culture: Postmodernist Perspectives

The multiplicity of cultures represented today in any given schoolroom or workplace has led applied linguists to adopt an approach to intercultural communication that takes into account the multiple, changing, and often conflictual nature of culture and intercultural relations. This way of looking at culture has been called poststructuralist, ecological, or postmodernist depending on which scholarly tradition it draws on. Because it no longer sees culture as a set of stable societal structures and national traditions, but focuses instead on culture as multiplicity, change, and power struggles, it has been called poststructuralist. For example, Norton (2000), drawing on feminist poststructuralist theory, has focused on the strategies used by new immigrants to draw on their multiple identities to resist marginalization in the workplace. Pennycook (2007) has illuminated the changed parameters of global popculture in the multilingual urban centers of late modern societies.

In language education, the fact that language learners increasingly do not agree on the definition of common tasks, do not share the same goals and values, the same historical memories, and interpretation of events as other speakers of the language, has prompted some applied linguists to adopt an ecological approach to the teaching of culture (Kramsch & Steffensen, 2008). They stress the relationality of self and other across multiple timescales in a decentered perspective, where the meaning of events emerges in a nonlinear way in interactions with others, and social reality is constructed minute-by-minute in the ongoing discourse.

Indeed, postmodern scholars are less interested in the notion of “identity,” that seems too stable and essentializing a term, than in the notion of “subject position,” which speakers and writers perform in discourse (Kramsch, 2009). In online or face-to-face interactions, students are seen as constructing their own and others’ subject positions through the questions they ask and the topics they choose to talk about. These subject positions constitute over time a discursive practice that we call “culture.” They are acted out on a much larger scale in national debates like, for example, the one surrounding the wearing of the Islamic veil in French public schools. This cultural debate cannot be taught in an American classroom through mere explanations of cultural difference. It has to be constructed with the students by making explicit the presuppositions behind their own religious beliefs; how educational history is constructed differently in the two countries; how French secularism is constructed in the American press; how freedom of religion is constructed in France and in the United States; and how the separation of Church and State is talked and written about on the global scale of Christendom and Islam.

In a postmodernist perspective, then, culture has become a discourse, that is, a social semiotic construction. Native and non-native speakers are likely to see their cultural horizons changed and displaced in the process of trying to understand others. A postmodernist definition of culture attempts to account for these new realities. If culture is no longer bound to the territory of a nation-state and its history, then we have to see it as a dynamic discursive process, constructed and reconstructed in various ways by individuals engaged in struggles for symbolic meaning and for the control of identities, subjectivities, and interpretations of history. As the postmodern sociolinguist Jan Blommaert (2005) has shown, these struggles take place simultaneously on multiple and conflicting time scales: the 21st century time of global ecological concerns clashing with the 20th century time of national industrialization and modernization as well as with the much older time of tribal territorial disputes and age-old cultural traditions. As “layered simultaneity” (Blommaert, 2005, p. 130), culture cannot be directly read into behaviors and events, it has a meaning that depends on who does the reading and from which historical position in society.

Conclusion

In sum, while culture has always been an indissociable part of language teaching, the links between the language taught and the sociocultural context in which it is used have become much more diversified than they used to be. These links are now defined by a host of individual, institutional, and ideological factors that render the task of the foreign-language educator particularly complex. The teaching of culture will always experience a tension between, on the one hand, the need for identifying, explaining, classifying and categorizing people and events according to modern objective criteria and, on the other hand, the desire to take into account the postmodern subjectivities and historicities that are becoming increasingly apparent in our decentered, globalized world. Both needs are reflected in language, which makes the task of the language teacher both more complex and more relevant than ever. The role of the applied linguist is to describe and explain this complexity and to suggest ways in which it can be turned into an educationally fruitful experience.

Teaching English as a Foreign Language in Kindergarten to 12th Grade

YUKO GOTO BUTLER

As English has increasingly gained prominence as a means of global communication, one can find various reforms in English education at the K–12 levels in those regions where English has traditionally been taught as a foreign language (EFL). While it is highly debatable whether the concept of EFL itself is valid (Nayar, 1997), the present entry defines EFL as English learning and teaching that takes place in *the expanding circle* wherein English traditionally has not had an institutionalized, official status (Kachru, 1992). There are various issues that have arisen as a result of such reforms at the K–12 levels in EFL education. However, due to the limited space available, I will focus on the following four issues: (a) the goals of English learning; (b) starting English education earlier; (c) instructional challenges; and (d) assessment.

The Goals of English Learning

In EFL settings, due to the increasing demands for global interaction in English, a command of English can be considered as “a near-universal basic skill” (Graddol, 2006, p. 15), rather than a luxury for elites or merely an academic subject to be studied at school. The governments in EFL regions see developing high proficiency in English among their citizenry as part of a larger national strategy. Acquiring a high degree of *communicative competence*, or developing the four balanced skills (i.e., listening, speaking, reading, and writing) for the purposes of social interaction, is often specified as one of the central goals of EFL education. The governments of some EFL regions, such as Europe, also feel that cultivating a new identity as a speaker of English as a lingua franca (along with other foreign languages) is an increasingly important part of the multilingual and multicultural education of their citizens (Jones & Saville, 2009).

In order to respond to such demands, EFL regions have undergone dramatic changes in their English education policies regarding their curricula, instructional practices, teacher-training programs, assessments, and accountability systems. Efforts have been made to develop benchmarks or standards within various nations as well as across nations, such as the Common European Framework of Reference for Languages (CEFR, the Council of Europe, 2001).

However, it is not uncommon to observe substantial gaps between the goals set by governments or standard-setting bodies and the actual implementation practices seen in classrooms. The very notion of communicative competence itself can be defined and understood in various ways and often can be a source of confusion among local educators. What should be considered as the target model, such as whether it should be *English as a lingua franca* (ELF) or a particular native-speaker model, is also a matter of debate among educators in many EFL settings. While the concept of ELF itself has gained increasing recognition among EFL educators, many of them still appear to have ambivalent feelings about implementing ELF in their own classrooms (Jenkins, 2007).

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0374

Concerns have also been expressed by policy makers and opinion leaders regarding the promotion of English in curricula. Some see this as a potential threat to students' native linguistic and cultural identities and feel that English can be a source of socioeconomic division both within a given region as well as across nations. It is a tremendous challenge for many policy makers to secure for their citizens equal access to English education, to allocate resources effectively, and to minimize regional achievement gaps among students and schools (e.g., Butler, 2009; Enever, Moon, & Raman, 2009).

Starting EFL Earlier

In order to develop higher proficiency in English, many governments in EFL regions have lowered the age at which EFL instruction begins. English as a foreign language instruction at the elementary school level, or even at the preschool level, has become increasingly popular in some areas.

The decision to start EFL instruction at successively earlier ages appears to be, in part, based on the assumption that children are better at learning languages. Despite the widespread belief in this assumption, however, empirical research to date concerning the relationship between the age at which foreign-language instruction begins and students' ability to acquire a given language still remains largely inconclusive. Applying the critical-period hypothesis (CPH) to foreign-language learning is not appropriate. CPH, in principle, is an argument regarding one's potential neurobiological mechanisms for acquiring critical abilities and skills for survival. However, foreign-language education often does not provide the learner with an opportunity to fully utilize such mechanisms. A number of factors other than age have been reported to influence students' learning. Such factors include: (a) the number of hours allocated for instruction; (b) the intensity of instruction; (c) the goals of language education programs; (d) individual learner factors such as aptitude, motivation, gender, and socioeconomic background (SES); (e) teacher qualifications; (f) resource availability and community support; (g) the local language environment; (h) how to define and measure "learning outcomes," and so forth (e.g., Nikolov & Mihaljević Djigunović, 2006).

Currently, there is substantial variation in early foreign-language education (including EFL) with respect to the goals set for students and actual teaching practices. However, we can roughly identify three major models for instruction: (a) the foreign-language experience or exploratory (FLEX) model; (b) the foreign language at the elementary school (FLES) model; and (c) the immersion model. The FLEX model aims to develop children's awareness of and sensitivity to various languages and cultures; this takes precedence over teaching the target language *per se*. FLES aims to develop children's foreign-language proficiency, usually with a special emphasis on the oral skill domains, as well as cultivate their cultural awareness. In some FLES programs, limited subject content (e.g., math and science) may be incorporated (such as is found in content-based FLES programs). In programs focused on teaching via immersion, the school curriculum is taught through the medium of the target language itself. Since the goals of these models are different, the expected outcomes should be defined accordingly.

Among the three models above, FLES is currently the most commonly employed around the globe. A review of the literature from various regions, however, indicates that FLES programs face a number of common challenges. The primary challenges include: (a) the limited time and resources available to support such programs; (b) insufficient training and support for teachers; (c) difficulties related to curricula and assessment designs; and (d) discontinuity in the ways in which such programs are implemented as students move from the elementary to the secondary school levels (e.g., Enever et al., 2009).

While research on EFL learning among young learners is still scarce in general, the major findings thus far include, but are not limited to, the following (e.g., Nikolov, 2000; Edelenbos, Johnstone, & Kubanek, 2006):

- The potential benefits of introducing EFL for young learners include not only linguistic development but also metalinguistic, cognitive, social and interpersonal development. Positive attitudes and enhanced motivation toward learning English have been consistently reported as the major advantages of introducing early foreign-language education.
- For children to have a higher level of motivation to learn a foreign language, they need activities which challenge them intellectually and give them a feeling of accomplishment, rather than merely having fun (e.g., playing games).
- Children's foreign-language development, both in terms of accuracy and fluency, is not steady but rather is complex and recursive.
- Evidence has shown that children benefit from receiving systematic reading and writing instruction from an early stage in their foreign-language learning, along with listening and speaking instruction. Children also can benefit from activities which focus on accuracy of forms and meaning, as well as activities focused on fluency.
- Children from the kindergarten level onwards can benefit from having opportunities to reflect on their own performance and strategies when using a foreign language.

Curriculum and Instructional Challenges

With the focus on developing students' communicative competence as a central goal of EFL education in many countries, *communicative language teaching* (CLT) has been widely employed in many recent EFL policy initiatives. Along with the promotion of CLT, various types of related instructional approaches and methods have frequently been promoted among teachers, including learner-centered teaching, task-based instruction (TBI), teaching English through the medium of English (TETE), and so forth (Holliday, 2005).

However, a number of studies have reported various difficulties in implementing CLT in EFL classrooms (e.g., Bax, 2003). The difficulties addressed in these studies appear to be largely attributable to two issues: one has to do with the conceptualization of CLT itself and the other has to do with the adaptation of CLT to local contexts.

First, there are different interpretations regarding what constitutes CLT, and the various choices and related approaches and methods have often been employed rather confusingly in EFL practices. CLT is commonly considered by teachers as being almost synonymous with the avoidance of grammar instruction, focusing on teaching speaking or the exclusive use of the target language or both (e.g., Littlewood, 2007). This may in part stem from the heavy reliance on grammar-translation-based instruction in the past. Some observers have also indicated that many activities introduced in EFL classrooms under the name of CLT are not communicative but rather are behavioral in nature (Grenfell, 2007).

Second, difficulties with implementing CLT also appear to arise when sufficient consideration is not given to local factors in its implementation. There are a number of local factors that may greatly influence teaching outcomes, including large class sizes, heavily form-focused high-stakes exam systems, insufficient resource availability, a lack of competency in this area among teachers, conflict with local cultural and educational values, and so forth (e.g., Fotos, 2005).

Various suggestions have been offered to EFL teachers to facilitate the successful implementation of CLT and other related approaches and methods. For example, Littlewood (2007) proposed a five-step model for adopting CLT where teachers in East Asia can gradually replace activities for "noncommunicative learning" with activities for "authentic

communication” (p. 247). It appears that when new approaches and methods are adopted locally, the process of *reinterpretation* and *adaptation* is essential. It is also important to note that no single approach or method, whether CLT or otherwise, works well across all contexts or under all circumstances (Prabhu, 1990; Butler, 2009).

Assessment

In response to increasing globalization and successive changes in the goals and instructional approaches in EFL at the K–12 level, various reforms in assessment have been undertaken in many EFL regions. Some of the most significant issues that have arisen from these reforms include: (a) the inclusion of oral assessments in high-stakes tests or accountability systems (or both); and (b) developing assessments that are aligned with the benchmarks and standards associated with EFL curricula, including various types of alternative assessments.

With regard to the first issue, as oral activities have increasingly become emphasized in EFL policy initiatives, efforts have been made to incorporate some form of oral assessment in in-house standardized tests or accountability systems in many EFL nations. Listening comprehension tests are frequently incorporated even in high-stakes norm-referenced standardized tests such as high-school exit or college entrance exams, many of which had focused heretofore almost exclusively on written language proficiency (i.e., reading, grammar, and writing). Speaking tests, although they are not yet very popular, have been incorporated in high-stakes tests in some nations, such as in the English foreign-language oral matriculation test in Israel. However, the effects of the inclusion of oral components in high-stakes standardized tests on instruction itself (i.e., the *washback effects*) do not appear to be as straightforward as one might expect in many cases (Cheng, Watanabe, & Curtis, 2004).

With regard to the second issue that has arisen with recent reforms in assessment, while norm-referenced standardized tests are still very popular in many EFL nations and regions, a growing number of EFL policy initiatives have adopted criterion-referenced approaches to assessment in which student performance is evaluated in relation to attainment levels, benchmarks, or standards. The aim of including such an approach is to create a direct alignment among curricula, instructional practices, and assessment. In some EFL regions, various types of alternative assessments such as teacher observations, portfolios, self-assessments, and peer-assessments are also included in their accountability systems. There is some indication, however, that the implementation of assessments that are aligned with benchmarks and standards also creates some dilemmas and challenges among different stakeholders.

Conclusion

EFL education has undergone drastic changes with respect to its goals, the starting age of instruction, instructional approaches, and assessments, all of which have changed to some extent in order to respond to the changing needs of learners and societies in an increasingly globalized world. Any innovative move in policy initiatives creates challenges and difficulties among different stakeholders. As a variety of Englishes have been created and developed, and as English has spread across the globe, various local factors continue to influence and be formulated into the implementations of EFL policy initiatives worldwide.

Teaching English as a Foreign Language to Students With Specific Learning Differences

JUDIT KORMOS

The Nature of Specific Learning Differences

In our globalized world, proficiency in another language is often as important as other basic competencies such as literacy and arithmetic skills. Therefore, it is of great importance that students who have special educational needs receive assistance not only in basic academic skills but also in learning foreign/second languages (L2). Providing these language learners with adequate support is especially imminent in the case of English, which has become an international language, and which is a foreign language most frequently taught in many countries of the world.

In order to understand the English-language-learning processes of students with specific learning differences (SpLDs), we first need to describe the types and characteristics of learning differences that constitute SpLDs. SpLD, a term currently used in the United Kingdom, highlights the view also endorsed by the United Nations Convention on the Rights of Persons with Disabilities (United Nations, 2006) that disability is a socially constructed barrier, which “may hinder full and effective participation in society on an equal basis with others” (p. 4). SpLDs are thus seen as differences in individuals’ abilities which might pose challenges in particular aspects of learning if their environment does not accommodate their needs. SpLDs include dyslexia, dyspraxia (motor coordination difficulties), dyscalculia (mathematics difficulties), ADD (attention deficit disorder) and ADHD (attention deficit hyper-activity disorder) (SpLD Working Group, 2005). It has to be noted, however, that both the terminology describing learning differences and their definitions vary from country to country. Although official figures show great variation, SpLDs are estimated to affect 5–20% of the population (International Dyslexia Association, 2002).

Among SpLDs, dyslexia is the most widely researched. One of the most influential definitions of dyslexia today is that of the International Dyslexia Association (2002), according to which:

Dyslexia is a specific learning disability that is neurobiological in origin. It is characterized by difficulties with accurate and/or fluent word recognition and by poor spelling and decoding abilities. These difficulties typically result from a deficit in the phonological component of language that is often unexpected in relation to other cognitive abilities and the provision of effective classroom instruction.

A number of etiological causes of dyslexia have been proposed, of which the most widely accepted one is that dyslexia is primarily a result of weak phonological processing skills, which result in difficulties with differentiating sounds, segmenting words into sounds, ordering sounds, and associating sounds with printed letters (Vellutino, Fletcher, Snowling, & Scanlon, 2004). These underlying processing problems do not only affect the acquisition of first language (L1) literacy skills but can also influence the success of second language acquisition (Sparks & Ganschow, 1993).

The Effect of SpLDs on the Cognitive and Affective Processes of Language Learning

In their linguistic coding differences hypothesis, Ganschow and her colleagues argue that “the primary causal factors in successful or unsuccessful FL learning are linguistic; that is, students who exhibit FL learning problems have overt or subtle L1 deficiencies that affect their learning of a foreign language” (Ganschow, Sparks, & Javorsky, 1998, pp. 248–9). It is widely acknowledged that L1 linguistic skills provide the basic foundation for foreign-language learning (Spolsky, 1989). For example, memory for verbal material helps us remember words in our first language as well as in a second language. Phonological short-term memory, which can temporarily store verbal information before it is encoded in long-term memory (Baddeley, 2003), aids in decoding sequences of sounds and associating them with words and their meanings, which is essential in learning reading and spelling both in L1 and in L2. Verbal reasoning skills are related to grammatical sensitivity, that is, the ability to identify the grammatical role of words in context, and inductive language-learning ability, which helps learners identify linguistic rules in the input. Both of these abilities play an important role in the acquisition of L2 syntax and morphology by helping students to discover rules and regularities of the language. These cognitive abilities are also the constituents of language-learning aptitude, which is a significant cognitive determinant of language-learning success (Carroll, 1981). Empirical research on the language aptitude of students with dyslexia indeed shows that students with dyslexia tend to score consistently lower on all the components of tests of foreign-language aptitude than those with no apparent signs of learning differences (e.g., Downey, Snyder, & Hill, 2000).

There is very little empirical research on the L2 learning processes of students with SpLDs other than dyslexia. Fletcher, Morris and Lyon’s (2004) study shows that students with dyscalculia also score somewhat lower than the expected standard on tests assessing phonological processing abilities. Jeffries and Everatt’s (2004) research also indicates that children with different types of SpLDs such as dyspraxia and ADHD might exhibit very similar cognitive profiles to children with dyslexia. Thus it can be assumed that learners with other types of SpLDs might also have lower language aptitude scores and experience difficulties in language learning. In addition, children with ADHD, dyslexia, and dyscalculia were found to have difficulties in sustaining attention (Fletcher et al., 2004). Attention is a key to language learning; therefore, the reduced attentional capacities of these students are expected to influence the success of second language acquisition. It also needs to be considered that different types of SpLDs often occur in combination and have different degrees of severity, which can result in varying levels of cognitive abilities underlying L2 learning, and hence in a continuum of language-learning difficulties (Sparks & Ganschow, 1993).

In addition to cognitive abilities, affective factors also play an important role in second language acquisition. Motivation, language-learning anxiety, and self-confidence are generally listed among affective factors that might potentially influence language-learning outcomes. Students with SpLDs, especially those with dyslexia, frequently experience failure in language learning, and consequently, they are at a risk of losing their motivation to learn foreign languages (Csizér & Kormos, 2009), develop symptoms of foreign-language anxiety (Piechurska-Kuciel, 2008), and might have low self-esteem and self-confidence (Crombie, 2000). In a recent questionnaire survey conducted with Hungarian dyslexic learners of English and German, Csizér, Kormos, and Sarkadi (2010) found that dyslexic language learners displayed significantly less positive motivational characteristics than their nondyslexic peers. They argued that “language learners with dyslexia might easily get caught in a vicious circle because of their problems in language learning, they lose their motivation, which then might lead to experiencing further failures.” The findings of

the study also indicated that dyslexic students have negative self-concept in the academic domain of language learning. Csizér et al. (2010) also conducted interviews with dyslexic English-language learners to examine their motivational characteristics. The interviews revealed that the motivation and language-learning attitude of students with dyslexia were influenced by the instructional setting. Teachers' general in-class behavior, method of instruction, and attitude to dyslexia were found to have an important effect on the students' language-learning attitudes and the effort they were willing to invest in language learning. These findings point to the high importance of instructional factors in creating favorable motivational conditions for students with SpLDs in L2 learning.

Dyslexia is often the cause of students' anxiety in academic contexts and in the private sphere of life. Piechurska-Kuciel (2008) investigated the English-language-learning anxiety of dyslexic students in a Polish secondary school context and found that dyslexic students displayed significantly higher levels of anxiety all through their language-learning career than their nondyslexic peers. The cognitive effects of anxiety might further aggravate the language-learning difficulties of students with dyslexia. Moreover, due to the anxiety-factors associated with foreign-language classrooms, when having the choice, students with SpLD might decide to opt out from language learning.

The Language-Learning Outcomes of Students With SpLDs

Dyslexic students show great differences in their cognitive abilities, which is also reflected in their achievement in language learning. In a study conducted in Norway, Helland and Kaasa (2005) found that dyslexic learners of English with good auditory processing skills performed worse than their nondyslexic peers only in tests of L2 spelling, grammar, and word reading, whereas dyslexic participants with poor auditory abilities scored lower on all the components of the English language test including L2 listening, speaking, vocabulary, grammar, and sentence reading. This shows that dyslexic language learners cannot be regarded as a homogeneous group of students, and their cognitive profiles have to be considered carefully in instructional programs and in assessment practices.

Among the other types of SpLDs, it is only ADHD that has been researched in the field of L2 learning. Sparks, Javorsky, and Philips (2005) found that if ADHD was not associated with dyslexia, students in US colleges with attention deficit performed just as well in language learning as their peers with no apparent signs of ADHD. Therefore, it would seem that ADHD alone might have little effect on the success of second language acquisition. We have to note, however, that in the case of younger children with ADHD, reduced attentional capacities might have a more significant impact on how much attention they can devote to various aspects of the linguistic input, and these students might experience problems in language learning.

Many language teachers and education policy makers believe that students with SpLDs, especially those with dyslexia, only have difficulties in acquiring spelling and reading in another language. Helland and Kaasa's (2005) research mentioned above, however, shows that students with severe symptoms of dyslexia seriously lag behind their nondyslexic peers in almost every component of English language proficiency, including grammar, vocabulary, reading, writing, and listening skills, and this finding was also replicated by Kormos and Mikó (2009) in a recent study conducted in Hungary. In an interview study Kormos and Kontra (2008) also asked language teachers with a wide range of expertise in teaching students with dyslexia what difficulties they noticed their students experience in language learning. They mentioned writing and spelling with the highest frequency, but they also gave account of problems in acquiring reading and listening skills, as well as vocabulary and grammatical knowledge. Kormos and Mikó (2009) also interviewed

Hungarian dyslexic learners of English, who reported the most serious difficulties in writing and spelling as well as problems with learning how to read in an L2 and remembering words and understanding grammatical rules.

Although we must not underestimate the difficulties involved in learning another language, especially English with its nontransparent orthography, we have to note that a large number of students with SpLD become competent L2 users. In our view, three factors are essential for the successful attainment of L2 skills. First of all, learners need a supportive classroom environment, in which the teaching and assessment methods are adapted to their needs. Second, innovative instructional methods using multi-sensory techniques need to be applied to facilitate the language-learning processes of students with SpLDs (see e.g., Schneider & Crombie, 2003). Third, students themselves must be aware that they can only overcome their difficulties if they invest sufficient energy and effort into the process of language learning. In many cases, the level of effort and persistence needs to be higher than for students with no SpLDs in order to compensate for the differential functioning of cognitive abilities needed for language learning. Finally, the notion of success might need to be reconsidered in the case of learners with SpLD and realistic educational objectives in language learning have to be established for these students.

Teaching English for Medical and Health Professions

BARBARA J. HOEKJE

The teaching of English for medical and health professions (TEMHP) is a growing enterprise worldwide linked to the rise of English as an international language of health care, global employment flows, and an increasing focus on communication in medical education and practice.

A great variety of medical fields are included under the heading of medical and health professions; major areas of focus have included physicians, nurses, pharmacists, and many other fields such as physical therapy and dentistry.

Following Maher (1986), two broad areas within TEMHP can be distinguished. TEMHP for academic purposes includes preparing learners for English-medium coursework in medicine, nursing, and other health-care programs, both in countries where English is a first or official language and, increasingly, in countries where English is a second or foreign language as well. TEMHP for occupational purposes includes preparing learners for occupational and professional activity such as conference presentations, research publications, and workplace communication. Because academic medical programs include clinical training, academic and occupational purposes overlap in clinical and other settings.

A further area within TEMHP focuses on the specific requirements of gate-keeping tests such as the US Medical Licensing Exam (USMLE) (Tipton, 2005), the Australian Occupational English Test (OET), and the UK Professional and Linguistics Assessments Board (PLAB).

Approaches to course development, teaching methodology, and materials have evolved within TEMHP as within ESP (English for specific purposes) in general. From an early concern with register analysis and features of medical texts (Maher, 1986), focus has shifted to the communicative needs of the target language use (TLU) setting, especially the clinical setting (Shi, Corcos, & Storey, 2001; Boshier & Smalkoski, 2002; Duff, Wong, & Early, 2002; Eggly, 2002). The communicative needs of the clinical practitioner are identified through ethnographic observations, interviews with major reference groups, and investigations of the attitudes and reflections of the learners themselves (Chia, Johnson, Chia, & Olive, 1999). Transcripts of spoken language as well as written medical texts are analyzed with discourse analysis approaches, including genre analysis, that extend beyond a focus on lexis only (El Malik & Nesi, 2008; Olmstead-Wang, 2009).

Teaching methodology in TEMHP has also evolved as in English for specific purposes. The development of learner autonomy is a key focus for TEMHP, where learners continue to face new and diverse contexts for communication throughout their professional lives. In a clinical interviewing course for international doctors, for example, doctors learn to monitor and improve their clinical interviewing skills through extended post-course video taping and review (Eggly, 2002). Well-sequenced instructional approaches can make use of information-gap and other activities to raise learners' awareness of critical language issues (Shi, Corcos, & Storey, 2001). Communicative approaches utilize role plays and simulations to provide opportunities for learners to practice the language of the TLU setting (Shi, Corcos, & Storey, 2001; Boshier & Smalkoski, 2002; Eggly, 2002).

An increasing focus on problem-based learning (PBL) within ESP supports learner autonomy and makes use of learners' content knowledge. A PBL approach is used, for

example, to develop learners' cognitive and linguistic strategies in a content-based academic English curriculum for premedical students in Brunei Darussalam (Wood & Head, 2004) and second-year doctors-in-training in Japan (Kimball, 1998). PBL approaches are taken in nursing and other health-care education programs as well.

With such a rapidly developing field, the need for texts and materials is growing. Published texts for communication within health-care contexts are increasingly available—both those designed specifically for the second or foreign-language course environment and all-purpose resources that can be adapted for ESP instruction, such as general texts for doctors on developing skills for communicating with patients. The Internet is a rich resource for authentic medical texts and materials such as those generated for professional medical conferences (Kimball, 1998; Olmstead-Wang, 2009). Such resources are increasingly available through free and commercial services. General resource Web sites offering orientation and pedagogical materials include the Web site of the Educational Commission on Foreign Medical Graduates (www.ecfm.org) for the US context; DoctorConnect (www.doctorconnect.gov.au) for the Australian context; and Englishmed (www.englishmed.com), sponsored by the Leonardo Da Vinci project for the European Union.

Course developers can increasingly turn to language corpora (e.g., the Cambridge International Corpus, www.cambridge.org/elt/corpus/cancode.htm, and the Nottingham Health Communication Corpus) as resources for actual language use between patients and health care providers.

A key area for further research within TEMHP remains the nature of the interaction of language, content, and culture within medicine and health care. In the globalizing contexts of English for medical and health-care purposes, communicative situations are increasingly complex. Clinical settings may be sites of multilingual language use where medical and nursing students negotiate between the languages of instruction, clinical practice, and patients. Shi, Corcos, and Storey (2001), for example, document the cognitive and linguistic complexity of language use in Hong Kong for medical students moving from Cantonese conversations with their patients to English with their tutors in an English-medium medical curriculum in Hong Kong. The cultural basis of health-care practice needs further recognition. In ESL (English as a second language) settings where there are large immigrant communities, TEMHP must take the multicultural, multilingual nature of the patient population into account (Bosher & Smalkowski, 2002; Duff, Wong, & Early, 2002).

Teaching for Internationalization and Critical Citizenship

JANE JACKSON

The trend of accelerating global interdependence presents both opportunities and challenges for communities, institutions, and citizens on all continents. Today's ever-changing world increasingly demands global competency, effective intercultural communication skills, and linguistic ability in more than one language, especially English, the global language of the 21st century.

In response to globalizing forces, including "market-driven neoliberal and neocolonial politics" (Kubota, 2009, p. 612), institutions of higher education around the world are reassessing their mission and responsibilities. Most have been grappling with the following questions: How can they raise their international profile and compete in this "knowledge economy"? How can they best prepare their students to become critical, global citizens and professionals in today's diverse world? How might they help students and faculty become internationally knowledgeable and interculturally competent? What steps can they take to provide students with a transformative international education? Similar issues are being addressed by international schools from kindergarten to 12th grade (K-12) and by other educational institutions at all age levels.

In some contexts change is largely motivated by economic imperatives. The General Agreement on Trade in Services (GATS) in North America, for example, has led to an emphasis on international branding and income generation (e.g., offshore campuses, distance education). Further, the dominance of English on the world stage is compelling many institutions with a less widely spoken language to adopt English as the medium of instruction in some programs to attract international students and generate much-needed revenue. Critics maintain that this is resulting in cultural homogenization, such as the domination of "Anglo-based academic standards and ideologies" (Knight, 2008), and the commercialization and commodification of higher education (Bassett, 2008; Knight, 2008). Kubota (2009, pp. 612–13) also argues that this trend is curtailing "the development of translingual and transcultural competency in foreign languages for English-speaking students."

Whatever the motivation (e.g., economic, sociocultural, linguistic, political, academic), institutions are realizing that students and teachers must be better equipped to contribute to their nation's effectiveness and competitiveness on the international stage. Besides the push for Englishization, in many quarters, there is growing awareness of the importance of mindful intercultural communication and responsible global citizenship to promote peace, stability, and cooperation in the world. Consequently, more and more institutions are embedding an international, intercultural dimension into their teaching and research.

Kälvermark and van der Wende (1997, p. 19) define internationalization as "any systematic sustained effort designed to make higher education more responsive to the requirements and challenges related to the globalization of societies, economy and labor markets." This process involves the integration of "an international, intercultural or global dimension into the purpose, functions or delivery of post-secondary education" (Knight, 2004, p. 11). In contrast with globalization, internationalization is more directly concerned with educational initiatives and linkages between countries that foster social, economic, political, and cultural

relationships. The term “internationalization” is usually linked to higher education, whereas “global” education is more commonly associated with K-12 schooling.

As institutions turn their attention to the preparation of globally competent students (and teachers), there is more awareness of the need to define what this actually means. What is critical citizenship? What knowledge, attitudes, and skills are needed for individuals to be globally and interculturally competent?

“Interculturally competent persons,” according to Chen and Starosta (2006, p. 357), “know how to elicit a desired response in interactions and to fulfill their own communication goals by respecting and affirming the worldview and cultural identities of the interactants.” For these interculturalists, intercultural communication competence is “the ability to acknowledge, respect, tolerate, and integrate cultural differences that qualifies one for enlightened global citizenship” (p. 357). For Fantini (2007, p. 9), intercultural communicative competence is “a complex of abilities needed to perform *effectively* and *appropriately* when interacting with others who are linguistically and culturally different from oneself.” Implicit in his definition are individual traits and characteristics (e.g., personality); the domains of relationships, communication, and collaboration; the dimensions of knowledge, attitude, skills, and awareness; proficiency in the host language; and a developmental process.

Like intercultural competence, global competence (sometimes referred to as “transnational competence,” “global citizenry,” or “global literacy”) is defined in numerous ways. For Olson and Kroeger (2001), a globally competent individual has adequate knowledge (e.g., understanding of cultures, languages, global events and concerns), perceptual understanding (e.g., open-mindedness, sophisticated cognitive processing, resistance to stereotyping), and intercultural communication skills (e.g., adaptability, empathy, cross-cultural awareness, intercultural mediation) to interact successfully across cultures in a globally interconnected world. The Stanley Foundation, an American organization which advocates peace and world citizenship, defines global competency as “an appreciation of complexity, conflict management, the inevitability of change, and the interconnectedness between and among humans and their environment” (see www.stanleyfoundation.org). From their perspective, “globally competent citizens know they have an impact on the world and that the world influences them. They recognize their ability and responsibility to make choices that affect the future.”

Hunter (2004) surveyed senior international educators, transnational corporation human resource managers, and United Nations officials to gather their views about the knowledge, skills, attitudes, and experiences necessary to become globally competent. For these individuals, a globally competent person is someone who is “able to identify cultural differences to compete globally, collaborate across cultures, and effectively participate in both social and business settings in other countries” (Deardorff & Hunter, 2006, p. 77). Global competence entails “having an open mind while actively seeking to understand cultural norms and expectations of others, leveraging this gained knowledge to interact, communicate and work effectively outside one’s environment” (Hunter, 2004, p. 74).

Based on this survey, Hunter (2004) developed the global competence model to provide a framework for international educators to prepare “global-ready graduates.” Central to his model is the belief that if one is to achieve global competency, one must recognize that one’s own worldview is not universal. This framework emphasizes that “attitudes of openness, curiosity, and respect are key starting points upon which to build the requisite knowledge and skills” (Deardorff & Hunter, 2006, p. 79). Davies and Pike (2009, p. 67) also maintain that “education has a key role to play in elucidating the concept [of global citizenry], nurturing a sense of allegiance at the planetary level, and preparing young people to play active and constructive roles in an interdependent world.” How might this be achieved in practice? What experiences, at home and abroad (both inside and outside the classroom), can promote global competency? How can teachers incorporate internationalization strategies

into their curricula to stimulate learning of this nature? What role can second language (L2) or foreign-language education play in the cultivation of critical citizenship?

An expanding number of institutions of higher education (as well as K-12 schools) are incorporating reflexivity and critical thinking components into the international/global dimension of their programs, including L2 education. Gacel-Ávila (2005, p. 125) maintains that critical pedagogy can stimulate “students’ awareness of a global perspective on human problems” and help them “to recognize and respect cultural differences.” As institutions play a central role in the formation of citizens and future professionals, this critical approach is vital to help prepare students for responsible citizenship in a global community. Critical engagement, self-reflexivity, and global competency are all important, and assessment practices need to be put in place that reward student learning in these areas.

In some institutions, internationalization efforts focus on the home campus; others offer study-abroad programs or international (faculty or student) exchanges, or both. In some cases, strategies and activities at home and abroad are connected and fully integrated, while in others, they remain separate domains. The term “internationalization at home” (IaH) refers to “the embedding of international/intercultural perspectives into local educational settings” (Turner & Robson, 2008, p. 15) with the aim of enhancing the global awareness, international understanding, and intercultural competence of teachers and “non-mobile” students. IaH initiatives aim to prepare individuals for life in an interconnected world whereby contact with people from other cultures (e.g., face-to-face, e-mail) is increasingly the norm.

For students, IaH usually consists of: courses and programs that have an international, intercultural, linguistic, global, or comparative dimension, or all of these (e.g., a “globalized” curriculum; L2 education with a critical, cultural dimension; multicultural or intercultural education; area, regional, cultural, or global studies; peace education); work placements or projects at international organizations; and the integration of local and international students both in and outside the classroom. Related extracurricular activities include international student clubs or international and intercultural events on campus, or both. Institutions may encourage students to participate in local cultural and ethnic community organizations through service-learning, internships, work placements, course projects, L2 tutoring, and applied research.

Instructional technology also facilitates IaH learning and intercultural contact. For example, e-lectures may be delivered by professors from multiple nations, students may use their L2 to collaborate on projects with counterparts at a foreign university, and the World Wide Web may connect students with foreign libraries and databases. The ease of virtual intercultural contact means that students and teachers on their home campus can now “journey” to other parts of the globe through the Internet, providing increased exposure to other languages and cultures.

A growing number of applied linguists (e.g., Guilherme, 2002; Byram, 2006, 2008; Birch, 2009; Jackson, 2010) are advocating a critical approach to foreign culture teaching/learning that will contribute to education for global citizenship. They recommend incorporating cultural content into language classes and the adoption of a critical approach to it. In particular, they stress the development of critical cultural awareness to stimulate deeper understanding and appreciation of self and other. In their promotion of language education for democratic citizenship, they recognize the importance of both reflective (subjective) and analytical (objective) cognitive processes and the cultivation of a more empathetic, open mindset.

Linked to critical citizenship is the notion of the “intercultural speaker,” which Byram (2008) refers to as the “outcome” of teaching for intercultural competence. He describes the intercultural speaker as “someone who is aware of cultural similarities and differences, and is able to act as mediator between two or more cultures, two or more sets of beliefs,

values and behaviors" (p. 75). More specifically, these individuals use their linguistic skills and sociolinguistic competence to develop intercultural relationships. These competent, flexible communicators "engage with complexity and multiple identities" and "avoid stereotyping which accompanies perceiving someone through a single identity" (Byram, Gribkova, & Starkey, 2002, p. 5). For Guilherme (2004, p. 298), *critical* intercultural speakers are able to "negotiate between their own cultural, social and political identifications and representations with those of the other," and in the process, become aware of "the multiple, ambivalent, resourceful, and elastic nature of cultural identities in an intercultural encounter" (Guilherme, 2002, p. 125).

Increasingly, educators are recognizing that intercultural competence and a deeper understanding of the global community are essential for students to become capable, engaged, critical citizens. Byram (2008) argues that "it is the purpose of FLT [foreign-language teaching] and the duty of teachers, not only to combine utility and educational value, but also to show learners how they can and should engage with the international globalised world in which they participate" (p. 229). Critical citizenship necessitates self-awareness, the motivation to become engaged, respect for self and other, and the acquisition of the skills and knowledge that facilitate constructive interaction with people from different parts of the globe. Through "intercultural citizenship" education (Byram, 2008), teachers can foster the requisite skills and understanding that characterize an international civil society. As Olson and Kroeger (2001) warn, "anything less than a global intercultural education places our students at a severe disadvantage as they go forth into our globally interdependent and interculturally complex world" (p. 135). Byram (2008) proposes that future foreign-language teaching proceed on the basis of this understanding; however, much more work needs to be done to translate these ideals into practice.

Teaching for Language Awareness

AGNETA M.-L. SVALBERG

Defining Language Awareness

Language awareness (LA) is defined by the Association for Language Awareness (ALA) as “explicit knowledge about language, and conscious perception and sensitivity in language learning, language teaching and language use” (retrieved April 19, 2011 from http://www.lexically.net/ala/la_defined.htm).

LA as “sensitivity” is the intuitive understanding of the effects of using language in particular ways. It is highly developed in good writers and gifted speakers. “Explicit knowledge about language,” on the other hand, allows a person to articulate what they know about language and ask questions about it, and this can facilitate and enhance language learning. But the relevance of LA is not limited to classroom language learning. It is a multidisciplinary and multidimensional field which covers affective, social, power, cognitive, and performance aspects, including language use and attitudes in wider society (James & Garrett, 1991). A recurring theme in LA work is the idea that exposure to and exploration of a language or languages is a worthwhile activity in itself which can contribute to cognitive development and intercultural understanding, and that it can facilitate further language interest and learning.

A term sometimes used as a synonym of LA, for example in van Lier and Corson (2008), is “knowledge about language” (KAL). There are also a number of terms equivalent to LA in languages other than English, for example *Éveil aux Langues* (French), *Sprachbewusstheit* (German), *Consciencia Lingüística* (Spanish), and *Språkmedvetenhet* (Swedish). Although each term has connotations specific to their context of origin, they all refer to the same general field of research and practice.

A Brief History of Language Awareness

The LA movement in the UK grew out of a concern about literacy issues, and about linguistic (in)tolerance (Hawkins, 1999). In the 1970s, the so called “Bullock Report,” *A Language for Life*, on the teaching of English in schools, emphasized the importance of language for all school subjects and had a major influence on this debate, as did work by a number of linguists, for example Michael Halliday’s text-based (rather than sentence-based) grammar, and John Sinclair’s pioneering work in corpus linguistics. By the 1980s, the term language awareness (LA) had become commonly used among education and language professionals (Donmall-Hicks, 1997), and there were a number of LA-inspired initiatives in language teaching in the UK. The government commissioned a project, Language in the National Curriculum (the LINC Project 1989–92) which produced language materials for schools (Carter, 1990). Their functional approach and inclusive attitude to non-standard varieties, however, clashed with prevailing views and the materials and recommendations were never implemented. The present National Literacy Strategy requires the explicit teaching of grammar, but does not necessarily lead teachers to adopt a LA pedagogy. Around the time of the LINC Project, in 1992, the Association for Language Awareness (ALA) was formed, with Eric Hawkins as its founder and inspirational driving force. The association,

DOI: 10.1002/9781405198431.wbeal1157

which has an international membership, publishes a journal, *Language Awareness* (Routledge), and holds a biennial international conference (www.languageawareness.org/).

In the rest of Europe, LA research and practice has been prompted mainly by multilingual contexts and fluctuating populations, with their concomitant linguistic richness and complexity. The French-led Socrates-Lingua funded project EVLANG (Éveil aux Langues) was, as the name indicates, concerned with the initial “awakening” stage of LA, and thus sought ways of promoting—in participating primary schools—an awareness of the local communities’ languages and cultures. It served as inspiration and model for a number of subsequent projects and for the EDiLiC (Education for Linguistic and Cultural Diversity) Association, founded in 2001, which consists of teams of teachers in a dozen European countries and beyond, doing practice based research in schools. The association organizes international conferences, sometimes in collaboration with ALA (www.edilic.org).

Language Awareness Pedagogy

Unlike traditional explicit approaches to language teaching, which rely heavily on teacher explanation and teacher input, LA requires learners to be active and inquiring. Language learners in a LA approach will typically be asked to investigate and discuss language, often taken from authentic text (i.e., text produced for purposes other than language teaching) and to draw their own conclusions on the basis of what they notice in the text.

Learners talking to each other about language is central. It is thought that the learners’ engagement with the language in such social interaction will facilitate learning. The teacher has a key role in setting up the students’ tasks so that they focus attention on a specific teaching point (e.g., a grammatical structure, or a social characteristic of language use). Underlying this exploratory approach, and the use of authentic text, is a view of language as ever changing and variable depending on its purpose and context, rather than as a body of fixed unchanging facts (Borg, 1994). Language is presented in context, and the learners are encouraged to analyze and talk about it in order to discover and formulate their new knowledge. Both cognitive and affective engagement are thought to be essential. Through social interaction the learners also acquire learning skills.

LA is compatible with language learning theories which place a particular value on explicit knowledge and learning. It builds on research evidence in the 1980s and 1990s which showed the importance of “noticing” and “attention” (Schmidt, 1990). Researchers point out that attention is a limited resource, so we are not able to notice everything in the language input. Noticing does not guarantee learning but learning does not happen without noticing. One way of finding out what learners notice is to set up tasks which they have to solve by discussing the language with each other. Research on learners’ talk about language in so called “language related episodes” seems to confirm the central role of noticing, and also highlights the importance of social interaction in helping learners construct knowledge (Swain & Lapkin, 2002). In this LA is essentially constructivist drawing on sociocultural theories of learning.

An issue in LA pedagogy is the role of terminology, or “metalanguage.” It seems clear that knowledge of, for example, grammar terms or rules does not necessarily lead to successful language learning (Alderson, Clapham, & Steele, 1997). Learners’ knowledge of metalanguage is, however, seen by LA teachers as a tool which can help them analyze and talk about language. The objective is not to memorize terms and rules but for learners to make connections between the forms of the language and their meaning and use.

Some techniques associated with a LA approach are *discovery learning*, *consciousness-raising*, *reformulation*, and *dictogloss*. Although the use of the terms varies, discovery activities tend to be more strictly guided than consciousness-raising tasks. Through carefully controlled examples, the learner is led to “discover” a particular rule or pattern of usage.

Consciousness-raising tasks, in contrast, are typically more open ended, and may not lead to one “right” answer. Learners might, for example, discuss the meanings and implications of modal verbs in a particular text. This will make them aware of the importance of the social and cultural context, for example the relationship between the speakers, in the use and interpretation of modal verbs. In “reformulation” the learners simply compare their own texts with a reformulation by the teacher. Dictogloss is a more elaborate way of creating the conditions for learners’ active noticing of language. It involves them attempting to reconstruct in writing a text which they have listened to while taking notes. They then compare the original text with their own version, noticing and discussing the differences they find.

Multilingualism and Intercultural Language Awareness

In classrooms as in society, multilingualism (including bilingualism and plurilingualism) is increasingly the rule rather than the exception. The dialects, varieties, and languages a person knows can be seen as a repertoire they draw on, rather than as totally separate and distinct language sets. Jessner (2008) argues that learning a third, fourth, and so forth, language is essentially different from learning a second language. The reasons are the more highly developed metalinguistic awareness of multilinguals (i.e., their conscious knowledge of and ability to analyze and describe language) and the complex dynamics of the languages in the repertoire. The languages of a multilingual person affect each other, develop, and sometimes decline (so-called “attrition”). Jessner employs dynamic systems theory (DST) to model multilingual language development. Many who are unfamiliar with DST have heard of the related *chaos theory* and the “butterfly effect”—theories which help us understand complexity (see also Larsen-Freeman & Cameron, 2008). In addition to these cognitive and learning issues, multilingual contexts such as international student communities or immigrant and host populations raise a number of sociolinguistic questions related to, for example, language and identity and language and culture (e.g., Kramsch, 1993).

With reference to the teaching of modern languages in the UK, Phipps and González (2004) argue that it is essential to shape a common “intercultural being,” and that talking about language and languages is central to this pursuit. Their approach is critical and constructivist. Critical LA (CLA), drawing on Foucault and others, focuses on language as an expression of existing power structures and how it constructs and perpetuates them, as illustrated in a paper by Fairclough (1999) on the discourse of global capitalism. The social and historical context is crucial. Pennycook (2001, pp. 94–100) describes CLA as critical discourse analysis with a pedagogic purpose (see also Norton & Toohey, 2004).

In a number of European countries, including Austria, Switzerland, Portugal, Greece, France, and Catalunya in Spain, education authorities have introduced LA into their school or teacher education curricula (Svalberg, 2007). Authors in Europe and beyond (e.g., Perregaux, 2006) argue for multilingual awareness in school settings, and the creation of a shared culture by drawing on the languages and cultures in the community. It is becoming accepted that language teaching and learning, including intercultural awareness, is essential for developing “intercultural citizenship” (Byram, 2008). At the same time, however, modern foreign languages in the UK are in decline. One initiative which strives to stimulate school pupils’ interest in language learning is the Foreign Language Awareness Group for Schools (FLAGS; University of Birmingham) which offers exposure to new languages in an e-learning format (<http://www.routesintolanguages.ac.uk/westmidlands/events/12-jan-09.html>).

LA is promoted as a means of overcoming or avoiding negative attitudes, and increasing tolerance and understanding between language communities. Language attitudes have been explored by researchers such as Lasagabaster (2003) and Garrett, Coupland, and

4 TEACHING FOR LANGUAGE AWARENESS

Williams (2003). Some government agencies and local authorities strive to raise awareness of linguistic issues in their respective bilingual or multilingual communities. In Ireland, the Institute of Public Administration has offered language awareness training for public servants which includes discussion of attitudes to and stereotypical views of the Irish language and its speakers. In Wales, the Language Awareness Infrastructure Support Service (LLAIS) was set up in 2006 to “ensure that health and social care research in Wales takes full account of the bilingual nature of Wales and its speakers; and to enhance the delivery of health and social care services to Welsh speakers in Wales” (www.llais.org). This is in recognition that the LA of health-care workers in bilingual settings can affect the quality of health care.

Conclusion

LA is conscious knowledge of and sensitivity to how language works. It involves noticing and reflecting on language form, meaning, and use. In teaching, LA is seen as a means of stimulating interest in learning languages, and making language learning more successful. With its emphasis on autonomy in language learning, and on cultural and linguistic respect and inclusiveness, it would seem to capture important facets of the 21st century zeitgeist, and to be of relevance well beyond the classroom. Critical LA can help us understand how language is used for political and other purposes, to persuade and manipulate us, and can help us use language more effectively to make our own voices heard. Finally, as bilingual and multilingual settings are increasingly the norm in the UK and in the world, a well-developed LA is becoming necessary in the workplace and in dealing with the public.

Teaching Grammar

DILIN LIU

Grammar instruction has always been an important, albeit controversial, component in language teaching, especially second language (L2) teaching. Questions related to grammar teaching include: what constitutes grammar teaching, whether grammar should be taught, which grammar description approach to use, which grammatical forms/rules to teach and in what order, when and how to teach grammar, what variables to consider in grammar instruction, what realistic results to expect, and what teachers should know/do to enhance grammar instruction. Debate about these issues has been framed and driven by new research findings and theories about language and language teaching.

What Constitutes Grammar Teaching?

Historically, grammar teaching has been viewed primarily as presenting, explaining, and practicing grammatical forms or rules as evidenced by the way grammar is taught in the Grammar-Translation teaching method and many traditional language-learning textbooks. In this view, grammar teaching typically begins with the teacher introducing/explaining a grammatical form (e.g., adding “s” to a singular regular noun to produce its plural form) followed by students practicing the target form in oral and/or written exercises. With new understandings about the role of *noticing* and consciousness-raising in language learning, however, the concept of grammar teaching has expanded to include any instructional activity “that draws learners’ attention to some specific grammatical form in such a way that it helps them either to understand it metalinguistically [i.e., in explicit linguistic terms] and/or process it in comprehension and/or production so that they can internalize it” (Ellis, 2006, p. 84). In this broader view, grammar teaching does not have to include explicit presentation/practice of a target language form. Instead, it can be any learning activity that draws students’ attention to the target form that will help them grasp it, even if the activity involves only comprehension since comprehension may eventually lead to production/acquisition.

Should Grammar Be Taught?

This question did not really become an issue of much debate until the 1970s when communicative language teaching, noted for its focus on communication skills and downplaying of the role of grammar teaching, emerged as a dominant teaching approach. The debate intensified when Krashen (1981) advanced his SLA theory, the monitor theory, which distinguishes between language acquisition and language learning and dismisses grammar instruction as unhelpful for language acquisition. According to Krashen, learned grammar, as conscious knowledge, does not contribute to language acquisition; it serves only as a monitor in language production when there is time to access it and the focus of the context is on form. Arguments against grammar instruction have also been made on the assumption that L2 acquisition, like L1 acquisition, occurs mostly as a result of the interaction between language input and universal grammar (UG), i.e., innate language

2 TEACHING GRAMMAR

knowledge. Evidence for the argument against grammar teaching came primarily from research findings in the 1970s that L2 learners follow basically the same order in acquiring language forms regardless of their L1 and learning conditions.

However, the anti-grammar-teaching position has since been seriously challenged. As reported in several extensive reviews of research on the effects of grammar instruction (Norris & Ortega, 2000; Ellis, 2006), many studies have shown that while grammar instruction may not affect the order of the acquisition of forms, it can, when appropriately done, accelerate acquisition rate and enhance learners' attainment, including their ultimate achievement, of accuracy and fluency. Furthermore, studies that compared explicitly instructed learners with implicitly instructed or uninstructed learners indicate that those who received grammar instruction, especially explicit instruction, appeared to gain a better command of the target structures and to progress more quickly in language development than those who received no instruction (Norris & Ortega, 2000; Ellis, 2006). Of course, as the reviewers of the studies caution, these research findings do not constitute completely convincing evidence for grammar teaching because (a) many of the studies assessed learning using restricted measurements with a focus on form (e.g., fill-in-the-blanks and sentence combination); and (b) the results of studies that measured learning using free, communication-oriented responses are not entirely conclusive. Yet, despite a lack of clear evidence for its usefulness, there has been a revived interest in grammar instruction since the 1990s as demonstrated by the many publications on the topic. The revival is not, however, characterized by a simple return to the old practice but marked by a passionate search for new, effective ways for grammar instruction that can help learners acquire their L2 more successfully.

Which Grammar Approach Should Be Used?

This is an essential pedagogical grammar question, for a key function of pedagogical grammar is to offer a description and analysis of the grammar of a language for the purpose of teaching/learning that language. The question is important because it can determine to a great extent which grammatical features to teach and how to teach them. Various grammar approaches have been used in L2 teaching. Before the 1970s, *prescriptive grammar* and structural grammar dominated as shown in the grammar-translation teaching method and the audiolingual method. Since the 1970s, these two rule-focused grammars have given way to an integrative *descriptive grammar* informed by various important contemporary linguistic theories, such as *systemic functional linguistics/grammar*. This integrative descriptive approach, best exemplified by Celce-Murcia and Larsen-Freeman (1999), treats grammar as a complex system involving not only form but also meaning and use (its contextual appropriateness). In this approach, the discussion of any given grammatical form will involve all three aspects because they are a closely integrated whole where "a change in one will involve a change in another" (Celce-Murcia & Larsen-Freeman, 1999, p. 4). Also, grammar teaching in this approach is discourse/content-based with grammar presented and practiced in coherent chunks of discourse rather than at the sentence level. Such an approach aims to help L2 learners grasp grammar as a resource they can use to make meaning effectively and appropriately in a variety of contexts. Grammar learning is thus as much about learning how to use language forms for communication as about learning language forms. It is a dynamic process that Larsen-Freeman (2003) calls "grammaring," through which L2 speakers learn to use grammar to communicate successfully.

More recently, two relatively new types of grammar approach have gained attention in L2 teaching: (a) *lexicogrammar* and *pattern grammar*, and (b) *cognitive grammar* and *construction grammar*. The two in each pair are grouped together because the second one in each pair

is in essence derived from the first. Lexicogrammar, an important component of systemic functional grammar, treats lexis and grammar as two inherently interconnected parts of one entity. Such a view has been supported by *corpus* research findings, which demonstrate that a grammatical structure is often lexically bound (i.e., typically composed of certain specific lexical items) and lexical items all have their own grammar in that they have their unique distribution in grammatical patterns (Biber, Johansson, Leech, Conrad, & Finegan, 1999; Hunston & Francis, 2000). Pattern grammar generates lexicogrammatical patterns from corpus data. By collapsing the boundaries between lexis and grammar, lexico/pattern grammars focus on fixed/semi-fixed structures formed by usage. Cognitive/construction grammars posit that language structures are generally not arbitrary but motivated by general human cognitive processes, and human language knowledge is not innate but usage-based. Such a grammatical approach views *form* as any syntactic, morphological, and prosodic patterns or symbolic units (collapsing the traditional boundaries among them) and *meaning* as a combination of lexical semantics, pragmatics, and discourse structures, for example, “*What’s up?*” is viewed as a symbolic unit for greeting based on its repeated use as such.

Thus in language teaching, as usage-based approaches, both lexico/pattern and cognitive/construction grammars focus on the study of lexicogrammatical patterns via ample actual usage examples. As an example, in teaching the English ditransitive structure (V+NP+NP), a corpus-based cognitive/construction approach would have students examine, in a corpus/corpora, the use of the prototype verbs in this structure/construction (e.g., *give/buy/teach*) and then generate, from the many relevant corpus examples, the usage/semantic patterns (i.e., the verbs typically used in this structure/construction due to its meaning restrictions), rather than generate/abstract the syntactic rule for forming the structure/construction (a traditional practice). Syntax plays little role in this approach, for a grammatical structure/construction is taught as a variable set of possible meaningful lexical combinations. Such a usage-based and meaning-/conceptualization-focused approach may make traditionally difficult-to-explain usages easier to explain and understand (e.g., a cognitive explanation for why both *gave a book to someone/give someone a book* are acceptable but we only say *gave someone a hug*, not *gave a hug to someone*, is that a “hug” is not something transferable and the person must be adjacent to the hugger to be hugged).

Which Grammatical Forms/Rules Should Be Taught and in What Order?

Superficially, this does not appear to be a difficult question because most language curricula and course books seem to embrace a comprehensive approach to grammar that proceeds typically from simple, regular, and/or useful grammatical forms to complex, irregular and/or less useful ones as defined by perceived utility to the learner. In reality, the question is very challenging and heatedly debated. Some language educators contend that only a few simple and easily applicable rules (e.g., the use of *s* in plural noun formation) should be taught because most of the other rules are too complex to be teachable. However, research has shown that learners, with proper instruction, can grasp very complex forms. Some other scholars believe that there are simply too many grammatical rules to teach and that many rules can be grasped by learners on their own. Hence instruction should focus only on forms that are difficult to learn. Yet determining which forms are difficult and warranting instruction is a very complex issue. First, there are two different types of learning difficulty: “(a) difficulty learners have in understanding a grammatical feature and (b) . . . the difficulty they have in internalizing a grammatical feature so they are able to use it accurately in communication” (Ellis, 2006, p. 88). As an example, most EFL/ESL

learners have little difficulty understanding the use of the past tense *-ed* but they often have difficulty using it correctly in a consistent manner.

So far, the latter type of difficulty has been largely overlooked in the selection of grammatical forms for instruction. The first type, difficulty in understanding a rule cognitively, has been the major consideration, but there have been competing theories about what constitutes such learning difficulty and which forms to include in instruction. The first major competing theory, founded on contrastive analysis, calls for teaching forms that are different from learners' L1 in meaning, structure, and/or distribution because these forms are believed to pose greater difficulty for L2 learners. This theory has proven problematic: research has shown that cross-language differences do not always present difficulty. The second theory, derived from universal grammar, advocates teaching marked forms because such forms are uncommon and hence more difficult to grasp than unmarked forms. However, markedness is not yet a clearly defined concept and hence not easy to apply. The third theory, grounded in error analysis, argues for using learners' persistent errors as a reference for selecting forms for instruction. A problem with this theory is that often the most persistent errors are not those that learners have difficulty understanding but those they have difficulty in using correctly in a consistent manner. One other related theory that has bearing on the issue is the *learnability/teachability* hypothesis (Pienemann, 1984). It assumes that grammatical forms are acquired in a certain order and, consequently, only forms that students are ready to acquire should be taught. Yet, in practicality, determining learners' readiness for a given form is not an easy task. In short, the question of which grammatical forms to teach and in what order still remains debatable.

When and How Should Grammar Be Taught?

Concerning when grammar should be taught, there are two schools of thought: one for teaching grammar early and one against it. The pro school has two main arguments: (1) L2 learners need to grasp some basic grammatical forms in order to engage in meaningful language learning; (2) lack of grammar learning initially often results in L2 learners using and developing incorrect language. The opposition also has two major arguments: (1) L2 learners often can develop some competence in the language without grammar learning; (2) many L2 learners who study the language in the classroom do not "progress beyond the initial stages of language learning" and will benefit more from natural learning in developing a "threshold communicative ability" (Ellis, 2006, p. 91). So far, there is no clear, definitive answer to this question.

Another question related to the timing of grammar teaching is when it should be done in a given lesson. Should it be carried out early in the lesson before most of the other activities, or after some interactive activities? Like the former question, this one does not have a clear, definitive answer, either.

The question of how grammar should be taught is very broad and complex because there are many variables and types of instructional practice that should be considered in answering the question. Given that the issue of how variables influence grammar instruction is very important in and of itself, it is addressed separately below. Regarding instructional practices, there have been a plethora of labels, including explicit/implicit instruction, task-based instruction, *focus on forms* versus *focus on form*, and inductive/deductive instruction. Due to space constraints, only the following types will be discussed.

Explicit Versus Implicit Instruction

Explicit instruction generally refers to the practice of explaining a target grammatical rule, often with the use of grammatical terminology, and examples of the rule that may include

negative evidence (error correction), or overtly asking students to notice, discover, and/or explain a target rule in the language input. In contrast, *implicit instruction* typically means the practice of providing learners with language input containing a grammatical structure enhanced or manipulated via one form or another, such as visual enhancement, to covertly draw learners' attention to the form. Explicit grammar teaching was the dominant practice in traditional teaching methods, but since the 1970s it has been seriously challenged and the implicit approach has been celebrated as a better choice. More recently, research has shown that both approaches can be effective if used appropriately, although explicit instruction is not appropriate for young children.

Inductive Versus Deductive Teaching

Inductive grammar teaching begins by providing learners with many examples of a rule for them to practice and then has the learners discover/generalize the rule on their own. In this approach, students usually provide rule explanations. Deductive teaching, on the other hand, commences by giving learners a rule and then has the learners apply the rules in various exercises. In general, the former approach is a better choice because (a) it conforms to the typical way humans learn, (b) discovery learning leads to better understanding and retention, and (c) students are more motivated when given the opportunity to discover rules than when being told the rules. Of course, some learners perform better with, or prefer, deductive learning due to their learning style and/or the freedom from worry about making errors in discovering/generalizing rules. Deductive learning is also often less time-consuming than inductive learning, which is an important issue for many L2 learners and teachers alike. Therefore, both inductive and deductive approaches can be useful depending on the learner and the context.

Input-Based Versus Output-Based Instruction

The distinction between input-based and output-based instruction is fairly straightforward: the former focuses on the comprehension of the form being taught and the latter on the production of it. An important new grammar teaching approach that can be classified as input-based instruction is *input-processing instruction* developed by VanPatten (1996), which is noted for its manipulation of the input of forms to have learners process it in such a way that they can effectively notice and grasp the form in the input.

What Variables Should Be Considered in Grammar Instruction?

Age, educational background, learning style, and proficiency level are very important learner variables. Learning goals and settings are some other important variables to consider in order to design effective grammar instruction in a given context. For example, explicit grammar teaching is obviously inappropriate for young children due to their limited cognitive ability. For learners with little formal education in their native language, overt instruction using metalinguistic terms is not beneficial, or not as beneficial as implicit teaching via structured input on form. While analytical learners may excel with explicit instruction, holistic learners often suffer under it. Similarly, intermediate and advanced learners gain more from explicit teaching than beginning learners. Concerning the variables of learning goals and settings, explicit grammar instruction is usually not helpful for newly arrived immigrants learning survival language, but it is often necessary for college L2 students learning reading and writing. In short, many variables have to be considered when deciding how to teach grammar.

What Realistic Results Should Be Expected?

Grammar learning is a long process. It may follow a U-shaped developmental pattern in which a learner produces a target form correctly in the initial learning stage, but then incorrectly, before finally becoming able to use it correctly again. Thus teachers should not expect learners to grasp a form completely after it has just been taught. Instruction may help learners notice the form and/or understand part of it, but often it will take more exposure/practice for them to develop a solid command of the form. Of course, the learning results and the time needed for the results to occur may vary from learner to learner, and from one grammatical form to another due to the difference in the level of difficulty.

What Should Teachers Know/Do to Enhance Their Grammar Instruction?

This is a very important question because teachers play a crucial role in the success of grammar instruction—an extremely challenging endeavor, as has been shown. According to studies on grammar teaching in teacher education (Liu & Master, 2003), besides possessing a solid knowledge of grammar and good teaching skills/techniques, teachers should empower themselves by engaging in critical examination of the grammar descriptions and instructional practices they use. They should also continually acquire new understandings about grammar and experiment, along with new teaching strategies and technology, because grammar instruction is an area that has experienced, and will continue to experience, rapid development.

Teaching Grammar and Corpora

TONY BERBER SARDINHA

Corpora have been used in teaching grammar for nearly 25 years (Willis & Willis, 1988). During this time teachers and researchers have discovered a growing number of benefits that seem to follow. Some teachers see corpus-based pedagogies as a means of encouraging independent learning, illustrating real uses of abstract rules, presenting authentic everyday grammar, promoting exploratory inductive learning. The manner of grammar presentation foregrounds the most frequent patterns, thereby lightening the burden on students by downplaying infrequent structures, breaking down the distribution of features across registers, and providing a fine-grained picture of grammar that leads to a nuanced understanding of structures (Johns, 1991; McCarthy, 2004; Biber & Conrad, 2010; Hughes, 2010; McCarten, 2010).

However, some teachers and researchers point out that using corpora in grammar classes often means teaching traditional clause grammar, it generally requires students and teachers to be tech-savvy, corpora cannot give negative evidence (i.e., show that something cannot occur), materials are difficult to generate, and examples can be decontextualized (see Ädel, 2010; Römer, 2010). To better understand these advantages and limitations, this entry describes the various approaches taken to the use of corpora for language teaching.

Corpus-Based, Corpus-Driven and Corpus-Informed Approaches

Grammar-teaching approaches can be distinguished as being either corpus-based, corpus-driven (Tognini-Bonelli, 2001), or corpus-informed (McCarthy, 2004).

In a *corpus-based* approach, structures or patterns to be taught are identified in a top-down direction; they are predetermined by reference to a particular theory, and the role of the corpus is to provide details about their frequency and distribution. In a grammar classroom, this will generally translate into tasks in which the teacher selects a particular grammatical feature and students then query a corpus for it. The corpus findings will then illustrate the uses of that feature.

In *corpus-driven* investigations, teachers and students start out with minimal assumptions about which structures to look for, and by relying almost entirely on basic units such as word and text, they search a corpus for recurrent patterns. In the classroom, this may materialize as bottom-up activities, such as data-driven learning tasks (Johns, 1991). In these, students generate hypotheses about the data or develop questions about grammar from other activities, analyze concordances, and confront their initial expectations.

The *corpus-informed* approach originated in applications of corpus linguistics to pedagogy, unlike the previous techniques, which emerged out of research. A basic principle is that “corpus data alone does not dictate an instructional syllabus” (McCarthy, 2004, p. 15). Consequently, materials writers are free to take actions that would be frowned upon in the two previous orientations, including adapting examples and sequencing teaching points regardless of their frequency in a corpus.

Direct and Indirect Means, and Examples of Research-Backed Materials

Broadly speaking, teaching grammar with corpora can be done in two ways: directly, when teachers and students handle corpora themselves, and indirectly, when materials writers and course designers analyze corpora and build their findings into grammar activities (Römer, 2010).

Direct applications generally include some form of corpus search results that are either produced in the classroom or prepared ahead of time by the teacher. The most typical corpus query tool used in these applications is the concordance. A concordance is a list of the occurrences of a string of characters, word, or expression in a corpus together with portions of the text in which each occurrence was originally embedded. The particular items that are searched for are defined by the aims of the course or class in question.

As far as *indirect* ways of using corpora for teaching grammar, there are a number of high-quality, research-backed materials that teachers and students can explore in grammar classes. For reasons of space, only three sets of these will be mentioned here.

The first one is the *Longman Grammar of Spoken and Written English* (LGSWE, Biber, Johansson, Leech, Conrad, & Finegan 1999), a large-scale comprehensive grammar entirely based on corpus-linguistics research. With a focus on linguistic variation, the grammar covers a wide range of traditional grammatical issues, from word classes to phrasal and clausal categories, but it also innovates by including topics such as the grammatical marking of stance, the grammar of conversation, and a detailed treatment on lexical expressions (bundles). Teachers can use the LGSWE in the classroom to describe most features of English grammar from a descriptive, not prescriptive, point of view. Being an academic grammar, it is perhaps best suited for very advanced or university-level classes. The many charts included in the grammar can prove very useful aids in presenting frequency information, especially by highlighting how frequently different features are distributed across different registers (conversation, fiction, news, and academic). There is also a simplified student version of LGSWE and a workbook. A recent addition is Conrad and Biber (2009), a volume that presents both theory and practice on a wide range of features, all deriving from corpus research. Its contents stretch from conventional issues such as verb tenses and definite articles, to unusual topics for a grammar, such as the noun “thing” and nonsexist language choices. This series can be described as both corpus-based and corpus-driven, since it often recognizes the validity of grammatical constructs, but it also illuminates them by specifying how they are realized lexically and how typical they are in each register, none of which had been predicted by theory. Since some language samples included in the practice books have been simplified where necessary, it also aligns itself with the corpus-informed approach.

The second set of materials is the *Collins COBUILD Grammar Patterns* series, which comprises volumes on verbs (Francis & Hunston, 1996), nouns, and adjectives (Francis & Hunston, 1998), as well as a workbook and a theoretical monograph (Hunston & Francis, 2000). This series is a prime example of corpus-driven research, since both pattern and meaning groups were arrived at from such basic units as the word and parts of speech.

The final series discussed here is *Touchstone* (McCarthy, McCarten, & Sandiford, 2005), a corpus-informed multilevel course-book series. In keeping with its philosophy, while it incorporates results from corpus-linguistics research, the authors are not bound by corpus statistics as they try to strike a balance between research findings and teaching methodology. Priorities are set by pedagogical principles and the corpus findings are added to the contents. *Touchstone* books look like traditionally prepared materials; corpus research remains essentially “under the hood,” and corpus-analysis tools are not visible.

In both teaching and research, however, what we see is that -informed, -based and -driven form a continuum, and that researchers, learners and teachers will normally move from one end of the spectrum to the other. For instance, a learner may begin exploring a corpus for reported speech from the corpus-based side, looking for “says/said that + personal pronoun + verb” and wind up at the corpus-driven end by discovering that certain verbs are more likely to follow “says” than “said”; verbs like “feel,” “see,” and “take” are more frequent with “says” whereas “need,” “expect,” and “wish” occur more often with “said” (according to the Corpus of Contemporary American English—COCA). Conversely, someone who starts out from the driven end of the continuum looking for “was + ing” may find out that many instances of this pattern will be used to report speech (“she was telling me . . .”) thus moving over to the corpus-based camp. But at the same time, as they look at concordance lines, they may discover that this particular realization generally involves reporting interesting news (McCarthy, 2004, p. 16), which will bring them back toward the corpus-driven end. And teachers may select and simplify corpus examples to best illustrate particular grammar points, which is consistent with corpus-informed principles.

Tools, Top-Down and Bottom-Up Corpus Handling

Handling corpora requires corpus-processing tools. Concordancers are the most popular of these. Two basic ways in which concordances can be used in grammar classes are the following:

- *Top-down approach*: This involves working deductively from a rule or structure down to the data or examples. Categories into which to fit the data may be presented before or after the analysis of concordances. One way to implement this is by having students analyze concordance lines and classify them into categories provided by the teacher.
- *Bottom-up approach*: This is characterized by inductive work, where no grammatical categories are assumed beforehand but are derived from patterns found in the data. Typically, teachers will first ask students to find patterns in a concordance and then interpret them in grammatical terms. These patterns may be formed by lexis, grammar, or both. Students may use previously learned features or propose new ones to account for the data. What is important is that the initial analysis is not restricted by a set of predefined categories.

The method of exploring concordances for grammar teaching in a bottom-up approach is not fundamentally different than their use for teaching other linguistic strata, such as vocabulary. This is because bottom-up analysis without a priori categories tends to highlight the lexicogrammar of the language.

In grammar teaching, however, the grammatical end of the scale is given prominence, thus highlighting structural properties of the patterns rather than word combinations.

In addition to string-based searches, teachers and students may do tag-based concordancing, provided their corpus has been tagged (coded). One of the most common tagged features is part of speech (POS), and several online corpora nowadays incorporate POS tagging. Unfortunately, there are many different tagging schemes, which may confuse students, but in general the tagging conventions are well detailed on most online corpora pages. POS tags can be very helpful in teaching and learning grammar, as they help students to pick up word classes and similar characteristics that would not be amenable to searching in a straightforward way without the tags.

4 TEACHING GRAMMAR AND CORPORA

In COCA (www.americancorpus.org), a query such as the following will bring up the most common verbs following “studies have”:

Words: studies have

Collocates: [v*]

Horizon: 0,2

The code next to “Collocates” is the actual tag that indicates “all verbs,” and “Horizon” refers to the position of the tag in relation to the first word being searched for, namely the second one to the right of “studies.” The results show a list of verbs and their frequencies, which include “shown” (N=1260), “been” (N=536), and “found” (N=452).

By choosing to display the results as a chart, the user will notice that the highest bar, by far, is that for the academic register, with 38.3 occurrences per million words. The chart will also reveal that the frequency of this pattern has risen over the last 20 years, from 8.4 per million in the beginning of the 1990s to 15.08 in 2005–10. Finally, by clicking on each chart bar, the user will obtain concordance lines for the corresponding section of the corpus.

The exploration of a corpus in this way can then be complemented by comparing the results of hands-on investigations with those published in reference materials. For example, Conrad and Biber (2009, pp. 7–9) have a unit on discovery verbs, including “studies have shown,” which can be explored in conjunction with the analysis of a corpus. This is one way in which direct and indirect methods can complement each other.

If students and teachers want to tag their own corpora, they can do so using a range of tools, some of which are freely available online. The TreeTagger, for instance, can be downloaded free of charge (www.ims.uni-stuttgart.de/projekte/corplex/TreeTagger/DecisionTreeTagger.html). A graphic interface can also be fetched and run with the tagger, simplifying the process of tagging individual files. An online version of TreeTagger is available at the CEPRIIL Web site (www2.lael.pucsp.br/corpora), for a number of languages. VISL (Visual Interactive Syntax Learning) is another popular tagger that can be accessed online (<http://beta.visl.sdu.dk>).

In addition to POS tagging, parsing or syntactic annotation is another type of markup that is very useful for teaching grammar. Whereas POS will enable teachers and students to retrieve word classes (nouns, verbs, adjectives, etc.), parsed corpora (sometimes also known as treebanks) will allow users to find syntactic constituents such as phrases or groups. For instance, the sentence “My best friend gave me chocolate yesterday” is represented in the Penn Treebank II as follows:

```
(TOP (S (NP-SBJ my best friend)
  (VP gave
    (NP me)
    (NP chocolate)
    (NP-TMP yesterday))
.))
```

(<http://www ldc.upenn.edu/ldc/online/treebank/README.intro>)

Syntactic constituents are represented each on a separate line, and both brackets and indentations reflect how each line is subordinated to the lines that precede it. So, “(S” refers to the top unit that was parsed, namely the whole sentence. This is then broken down into a noun phrase functioning as subject of the sentence (NP-SBJ my best friend) and a verb phrase (VP) that comprises the remainder of the sentence. This VP is then further subdivided into three separate NPs (me, chocolate, yesterday). As with POS-tagged

corpora, parsed corpora differ among themselves in terms of the conventions followed for parsing. Students and teachers may find parsed corpora much harder to use than plain text or POS-annotated ones. Again, fortunately, documentation is available on some treebanks, which can be helpful for teachers who want to introduce parsing into grammar teaching. Currently, however, there is a shortage of materials on how to use treebanks in the classroom, and as a result they remain largely ignored in teaching grammar.

An exception is VISL, which offers a graphic interface for searching previously parsed corpora as well as for allowing users to annotate their own corpora automatically. VISL was designed with classroom practitioners in mind, and because of that and its visual appeal, it may be easier to incorporate into grammar teaching than other treebank resources. For instance, Java tools enable users to see parsed sentences as trees rather than plain text, which will perhaps look more familiar to students and teachers.

Caveats

Some caveats to using the tools and techniques surveyed here should be noted.

First, as far as infrastructure goes, some preconditions need to be met—the most obvious of which is access to computer facilities; accessing an online corpus entails an Internet connection; using concordances in the classroom requires copying and/or some form of projection by beamer or electronic board. There is a digital divide in the world, meaning large numbers of people have very limited access to technology (Hughes, 2010, p. 407), but there are alternatives where such infrastructure is scarce. One is concordancing by hand on a blackboard (Willis, 1998); another is accessing free online corpora in Internet cafes or LAN houses.

Second, with regard to levels of proficiency, it is important to bear in mind:

- *Searching online corpora*: This is not likely to prove challenging to most students, especially the generation Y, given the similarity to searching the Web. Most beginners should experience no problems.
- *Concordance analysis*: Short lines and lack of context may hinder comprehension. Learning to read concordances requires training. Perhaps most appropriate for intermediate and upper levels of proficiency.
- *Part of speech tagging, parsing, treebank searching*: These are very sophisticated techniques that require both technical skills and theoretical knowledge. As such, best suited for advanced students, and possibly most appealing to students with a background in hard sciences.
- *Corpus-based and corpus-driven materials*: Most of these materials are better suited for advanced classes.
- *Corpus-informed materials*: These tend to cater for students at all levels.

Finally, most activities involving corpus materials are probably best described as traditional PPP (presentation, practice, production) tasks. These normally incorporate some form of explanation or noticing, followed by question and answer, gap filling, matching or sentence completion. Concordances are usually gapped, and students have to fill in the missing words. Oddly, for an area that relies on technology, corpus linguistics does not live up to its expectation in the classroom. Teaching materials are essentially paper-based, and reflect the tools used by researchers in their trade—basically texts, concordances, frequency lists, and taggers. They could be made more effective by incorporating a wider range of visual technologies, such as word clouds, charts, and animation, and exploring different kinds of text in the classroom, such as online video, video games, and music (Berber Sardinha, 2010).

Teaching Indigenous Languages

BARBRA A. MEEK

Introduction

In the introduction to the edited volume, *Teaching Indigenous Languages*, Dr. Jon Reyhner reflected that “I have written on this subject of maintaining and renewing indigenous languages before . . . but the recent work of Dr. Evangeline Parsons Yazzie and Dr. Richard Littlebear . . . has crystallized for me the centrality of this effort for the survival of indigenous peoples” (1997, p. v). This survival, according to Reyhner and those he cites, is characterized by the sense of well-being, safety, and belonging that accompanies the knowing and speaking of a familial language, the language of one’s ancestors, and the language of one’s family. Therein lies the challenge for indigenous language educators, activists, and supporters, the challenge of teaching a language effectively enough to stimulate a sense of belonging and of fulfilling the ultimate goal—indigenous (language) survival.

Reyhner, founder of the “Stabilizing Indigenous Language” symposia, and many of the people who have participated in these symposia, have been working toward this goal since well before the inception of these meetings in 1994 and regularly thereafter. The sentiments of these participants, which emphasize the critical link between language, cultural well-being, and human rights, have recently been underscored by the United Nations’ Declaration on the Rights of Indigenous Peoples, or DRIP, which positions language as central to the rights of indigenous peoples and the responsibility of nation-states to protect it. Article 14 spells out this commitment:

States shall, in conjunction with indigenous peoples, take effective measures, in order for indigenous individuals, particularly children, including those living outside their communities, to have access, when possible, to an education in their own culture and provided in their own language. (<http://www.un.org/esa/socdev/unpfii/en/drip.html>)

While the purpose of this entry is to provide a general overview of the literature, the central concern focuses on the ways that these linguistic rights may facilitate the linguistic practices—the “small” steps—taken toward teaching, acquiring, and sustaining indigenous languages. As Reyhner’s reflection highlights, maintenance and renewal are not simply about learning a language; they are about socialization into an entire cultural grammar.

Core Issues

In the past decade, a wealth of literature has emerged addressing the ideological and practical challenges of indigenous language instruction. For the most part, this literature builds on and continues to systematize the earlier work on language shift, the process whereby a marginalized language begins to shift away from being a community-wide everyday vernacular to being a more esoteric, specialized code known only by elder community members. This process is articulated most notably in Joshua Fishman’s book, *Reversing Language Shift* (Fishman, 1991), a stage-by-stage guide to assessing and reversing

2 TEACHING INDIGENOUS LANGUAGES

the shift of indigenous and minority languages. Any substantial reversal of such language shift requires the recovery of a sustainable speech community.

Toward that end, the literature offers a range of approaches for teaching indigenous languages, many designed according to the age and grammatical competence of the participating individuals. To inspire novice child speakers, especially preschool-age children, immersion programs are recommended, frequently modeled after the “language nests” used to revitalize Māori and Hawaiian languages (King, 2001; Wilson & Kamanā, 2001). For older children, immersion models as well as more school-based programs have been developed, incorporating a literacy and a cultural component into the indigenous language curriculum (e.g., Eder, 2007) as well as translating other courses and pedagogy into or through the indigenous language (e.g., Harrison & Papa, 2005). For adults, university-based classes, community-based workshops, language camps, and master–apprentice programs have been implemented in order to entice adult speakers to speak the indigenous language again and to facilitate nonspeakers to speak it for the first time (e.g., Hinton, Vera, & Steele, 2002; Morgan, 2005). However, not all indigenous languages have become imperiled equally. Indigenous languages still spoken may require the development of more sophisticated instructional materials, techniques, and curricula that can rival the educational experiences offered in more dominant, usually European, foreign-language classes. “Sleeping” languages, on the other hand, require archival research for grammatically and verbally reconstituting the language prior to the development of any curriculum materials or immersion programs (Hinton & Hale, 2001). Thus the specific goals and techniques of these indigenous language projects may vary.

Four Challenges

While the specific goals and techniques of indigenous language projects may vary, many of the challenges remain and are rooted in the variability of the resources, the materials, and the institutions which structure the teaching of indigenous languages. Four prominent issues pervade the literature on teaching indigenous languages: the entanglements of the literacy–orality debate; the marginality of indigenous language texts; the development, accessibility, and use of language media; and the overall management of and support for indigenous language teaching. In other words, what materials and routines can and are used, how do these techniques encourage or discourage community participation, and how are such teaching programs evaluated, supported, and controlled?

Literacy has long been an issue in indigenous language development. On the one hand, literacy projects create space for documenting indigenous languages, for creating curriculum materials, and for incorporating indigenous practices into dominant institutional domains. On the other hand, some indigenous people argue that their heritage languages are orally based and therefore inappropriate for entextualization and the project of literacy. An oft-cited case illustrating this stance is that of Puebloan groups and their approaches to language teaching (Benjamin, Pecos, & Romero, 1997). The challenge for teaching involves the development of effective verbal techniques that encourage acquisition and the integration of culturally relevant activities that inspire speaking but respect the sociological constraints on the performance of certain genres of speaking at certain times or by certain individuals (Eder, 2007). Immersion programming has made significant strides toward addressing the needs of an orally based approach.

Where literacy and writing are pedagogically welcome, the challenge resides in the development, manufacture, and distribution of useful, engaging language materials, texts, and other media. One of the issues to consider in the creation of language materials is the formatting of the indigenous language in relation to the dominant language. Many indigenous language materials are locally made by indigenous language teachers, though

in some cases, state-funded materials have been produced. Even so, their appearance, level of detail, and topical breadth pale by comparison with state-funded, mass-produced textbooks. Marginalizing their linguistic appearance further is the prominence of the dominant language within the indigenous language texts. One strategy for interrupting this dominance is to minimize the prominence of the dominant language (for glosses only) or to entirely remove the dominant language from the text (Meek & Messing, 2007). Additionally, more than one dialect may exist within a language community. How will this linguistic diversity be accommodated, and how will new words be created? This issue again complicates the development and manufacture of language media.

Another issue is accessibility: Who will have access to the media and how will they use it? And, more specifically, how will such media encourage acquisition? One case illustrating the challenges of media development describes how competing ideologies about language ultimately can discourage the use of media like the Internet because such methods for teaching language (and culture) contradict community-wide philosophies of learning and socially sanctioned trajectories of acquisition (Nevins, 2004). People, especially older adults, felt threatened by the new technologies being used to transmit their language because they disrupted ordinary interactional means of transmission and the structuring of authority between older and younger generations implicit in these means. The issue of authority also surfaces in relation to the training and credentialing of teachers where the challenges are the opportunities and resources individuals have to acquire the necessary credentials and background in order to become teachers and to have a rewarding experience (Hinton & Hale, 2001). By extending indigenous language learning to institutional venues, dilemmas over authority, power, and control emerge, exacerbated by the funding and resource requirements demanded for the creation of media and the facilitation of training and access.

This illustrates that the final challenge for teaching indigenous languages inevitably resides within the political economy surrounding indigenous language efforts (see Sims, 2005). In order for indigenous communities to develop programs, train instructors, and maintain educational continuity, resources and funding are critical. The United Nations' appeal to nation-states for the recognition of indigenous groups' rights to self-determination begins to offer an opportunity for indigenous groups to mobilize support and to force dominant regimes to support their efforts. However, establishing funding to sustain their progress is just one step. With funding comes expectations and struggles over control and accountability. As tribes and other indigenous groups begin to articulate their own educational goals and protocols, these struggles will hopefully diminish, but until such accommodations, cooperative agreements, and collaborations have been established, this broader challenge for teaching indigenous languages remains.

Conclusion

Reflecting on the survival of Navajo, Bernard Spolsky highlighted "the importance of seeing language and education in the full social, cultural, religious, and political context," noting that "if efforts to reverse language shift are to be successful, they must target and transform multiple forces and institutions in each dimension of this context" (2002, p. 157). Ultimately, for each indigenous community, the challenges and solutions will be realized in a variety of ways, impacted by the different language ideologies in circulation (Echeverria, 2003) and the various opportunities that indigenous communities will have to realize linguistic sustainability.

Teaching Integrated Skills

ALAN HIRVELA

Introduction

Teaching foreign-language skills in an integrated way—that is, with what is sometimes called a “blending” of the skills within a teaching/learning event as opposed to teaching them separately from each other—traditionally was not seen as an option by language teachers. Instead, the focus was on teaching a single skill at a time. This was due in large part to the domination of the ubiquitous and venerable grammar-translation method, with its emphasis on building grammatical knowledge and control (Kelly, 1969; Howatt, 1984). Richards and Rodgers (2001) and Stern (1983) show how, in the mid- to fairly late 20th century, the emergence of the oral proficiency-oriented audio-lingual method likewise stressed a single skills emphasis in language teaching. What Widdowson (1978) called the “conventional pedagogic practice” during that period worked on a basic principle that “appears to be an adherence to segregation rather than integration: ‘divide and rule’ . . . language teaching commonly consists of units in which ‘comprehension’, ‘grammar’ and ‘composition’ appear as separate sections, and language practice books tend to be based on the same distinctions” (p. 144). Thus, the core skills of speaking, listening, reading, and writing, along with closely related skills areas such as grammar and vocabulary, were taught in isolation from each other.

The evolution of the field of applied linguistics during that period, coupled with the Hymesian notion of “communicative competence,” played a pivotal role in changing this “divide and rule” orientation to language teaching theory and pedagogy. Embedded in the notion of communicative competence is the *reciprocity* between language skills that constitutes real-life communication. From communicative competence came the popular teaching approach called communicative language teaching (CLT), where the ability to communicate meaningfully in the target language became the focus of pedagogy.

CLT, with its emphasis on discourse as opposed to isolated or decontextualized sentences, and on real-life communication as opposed to mere accumulation of knowledge of the target language, allowed for the creation of teaching approaches which asked learners to draw on different language skills (instead of just one) in order to fulfill a communicative purpose. Thus, what Widdowson (1978) calls the “principle of integration” took center stage in the communicatively oriented classroom, and applied linguists and language teaching specialists set about generating frameworks, activities, and materials that called for the combining of language skills. This “principle of integration” revolves around the idea that language learners must learn how skills work together in the production and reception of discourse and thus how to use those skills in such ways.

Why Not Teach Skills in Isolation?

One way of looking at language instruction, the one that, as noted earlier, has dominated the history of language teaching, is the *segregated* skills approach. In this approach, teaching is oriented toward one skill at a time. Oxford (2001) notes that this can also be called

2 TEACHING INTEGRATED SKILLS

the language-based approach “because the language itself is the focus of instruction” (p. 1) rather than actual use of the language. In addition to the perhaps intuitive appeal of such an orderly, systematic way of teaching language is the fact that there are instances in which learners need only one particular skill. For example, scientists in non-English-dominant countries may require the ability only to *read* English so as to stay informed about new developments in their field via its professional literature.

However, as Oxford (2001) observes, in this approach “the emphasis is not on learning for authentic communication” (p. 1). This, she says, “is contrary to the integrated way that people use language skills in normal communication” (p. 2). Thus, unless the goal of language instruction is to address a very specific need of the kind described earlier, the segregated skills approach will leave learners ill-equipped to actually use the target language. They will, as Widdowson (1978) famously asserted in one of the influential early critiques of such instruction, acquire knowledge of formal *usage* of the language rather than genuine ability to *use* it for communicative purposes. The integrated skills approach addresses this need for an emphasis on *use*.

Approaches to Integrated Skills Instruction

One way to look at integrated skills instruction is to say that skills can be taught in a *semi-integrated* approach featuring restricted combinations of skills. This is most commonly seen in combined speaking and listening courses, or courses combining reading and writing. Other combinations are also possible, as illustrated recently in Weissberg’s (2006) book *Connecting Speaking and Writing in Second Language Writing Instruction*. In essence, any combination of skills is possible. Underlying this semi-integrated approach are two fundamental and overlapping beliefs: (1) that the skills involved draw upon the same core sets of underlying skills and processes, and (2) that each of the primary skills is normally used in conjunction with the other. Writers, for example, often draw from source texts read (e.g., newspaper articles, Web site essays) as they compose, while readers may use writing to make sense of reading (e.g., taking notes, writing annotations in the margins of a text). In a similar vein, learners can be taught to use writing to enrich listening for purposes such as attending academic lectures.

The other way to look at skills integration is the *fully integrated skills* approach, in which teachers seek to have students use more than two skills in the production of discourse. This is where the notion of “blended” skills is fully operative. This is because, say Peregoy and Boyle (2005) while discussing the linking of listening, speaking, reading, and writing, “In natural, day-to-day experience, oral and written language uses are not kept separate and isolated from one another. Instead, they often occur together, integrated in specific communication events” (p. 120). In this way, explains Oxford (2001), learners are exposed to “authentic language,” and this “challenges them to interact naturally in the language.” As a result, “Learners rapidly gain a true picture of the richness and complexity” of the target language (p. 2).

Applications of Integrated Skills Pedagogy

Oxford (2001) notes that, whether in the semi-integrated or fully integrated formats, there are two principle applications of integrated skills pedagogy. *Task-based* instruction is one of them. Hirvela (1987) illustrates this approach in his communicatively oriented “designing a dog-exercise machine” task in which students, working in small groups, must develop a design for such a machine. Reading, writing, listening, and speaking blend together in various alignments as the students discuss their emerging design (linking speaking and

listening), write a description of it and read drafts while doing so (writing and reading), and present their design to the class (speaking), which also involves listening and responding to questions about the project. Thus, the completion of this kind of task necessitates use of all the major language skills, and never in isolation from one another. This kind of approach generates communicative competence as students interact simultaneously with various language skills.

The other major application of integrated skills instruction, according to Oxford (2001), is the *content-based* form of pedagogy. While the task-based approach “stresses doing tasks that require communicative language use,” she says, content-based language teaching “emphasizes learning content through language” (p. 1). This entails the use of various combinations of language skills while performing activities related to learning subjects such as history, math, and science. As Brinton, Snow, and Wesche illustrate in their 1989 book *Content-Based Second Language Instruction*, there are different ways in which foreign-language and content area teachers can work together to ensure that students acquire the skills combinations required in the acquisition of content area knowledge and ability.

Conclusion

Widdowson (1990) explains that “all pedagogy is involved in some kind of grading or ordering to allow for the gradual development of learning” (p. 120). The integrated skills approach does so by promoting *interaction* between language skills. How the skills combinations are “ordered,” and how extensive the combinations are, depend on the goals of the language course and the needs of the learners. Integrated skills instruction creates opportunities for learners to experience the reciprocity that exists between language skills. In this way they experience language holistically, rather than in isolation, and are better equipped to use their language skills effectively in the ways in which they are employed in real-world contexts. Teaching language skills in this integrated manner has been an important feature of language teaching pedagogy since the communicative movement took root in the early 1980s, with specialists continuing to find newer and richer ways to generate interaction between the skills learners must acquire.

Teaching Language for Academic Purposes

KEN HYLAND

Introduction

Language for academic purposes teaching refers to a distinctive approach to language education based on an identification of the specific language features, discourse practices, and communicative skills of target academic groups, and which recognize the particular subject-matter needs and expertise of learners (Hyland, 2006).

The growth of diversity in the students entering universities in many countries as a result of widening access policies, the increased attention given to effective teaching by funding bodies, and the incentives of offering English for Academic Purposes courses to fee-paying students from around the world, have all contributed to the growth of this sector. Accompanying these developments, moreover, has been a growing awareness that academic communication presents considerable difficulties for many students. The communicative demands of the modern university involve far more than simply controlling language errors or perfecting an “academic style.” Supported by an expanding range of publications and research journals, there is a growing awareness that students, including native speakers of the language of study, have to take on new roles and engage with knowledge in new ways when they enter university (Prior, 1998; Hyland, 2009). They quickly find that the language they use to write essays, read textbooks, and understand lectures differs considerably from that which they are familiar with in their homes and workplaces.

Teachers now acknowledge that the complexity and immediacy of these challenges cannot be addressed by some piecemeal remediation of individual error. We no longer see students’ difficulties as a linguistic deficit which can be topped up in a few language classes, but have come to regard teaching language for academic purposes as developing new kinds of literacy, equipping students with the communicative skills to participate in particular disciplinary contexts. Pedagogic practices therefore attempt to offer systematic, locally managed approaches which draw on a number of key ideas, the most important of which I set out below.

Needs Analysis

Needs analysis refers to the techniques for collecting and assessing information relevant to course design: it is the means of establishing the *how* and *what* of a course. While not unique to teaching languages in academic contexts, the use of systematic means to define the specific sets of skills, texts, linguistic forms, and communicative practices that a particular group of learners must acquire is central to it. Needs analyses inform its curricula and materials and underline its pragmatic engagement with occupational, academic, and professional realities (e.g., Dudley-Evans & St John, 1998). Needs can involve what learners know, do not know, or want to know, and can be collected and analyzed in a variety of ways, mainly drawing on questionnaires, observations, tests, and text analyses (e.g., Brown,

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1162

1995; Hyland, 2003). Its importance recognizes the diversity of both students and disciplines. Research shows, for instance, that the kinds of genres students have to write, the ways these are constructed, the style of lecture delivery, and the assessment practices they need to master all differ considerably across disciplines (Hyland & Bondi, 2006).

The concept of *need* has been expanded beyond the linguistic skills and knowledge required to perform competently in a target situation. On one hand it now includes *learner needs*, or what the learner must do in order to learn, incorporating both learners' starting points and their perceptions of need (Hutchison & Waters, 1987). More recently, the question of "whose needs?" has been asked more critically, raising questions about target goals and the interests they serve rather than assuming they should exclusively guide instruction. The term *rights analysis* has been introduced to refer to a framework for studying power relations in classrooms and institutions and organizing students and teachers to bring about greater equality (Benesch, 2001, 2009). The importance of needs to teachers is that it means understanding learners and target contexts, discourses, and socio-political contexts.

Collaborative Pedagogies

A second feature of teaching languages for academic purposes is the desirability of working in tandem with members of the specialist fields it seeks to describe and teach, adding subject specialists' skills and knowledge to the language teacher's expertise in communicative practices. This allows the topics, content, and texts of the profession to act as vehicles for teaching particular discourses and communicative skills.

Students bring to their classes some knowledge of their specialist fields and the kinds of communication that go on within them, and this implicit knowledge is useful in a number of ways. One way is that it encourages teachers to draw on students' specialist expertise to promote relevant communicative activities in the classroom, particularly through relying on tasks and materials that display authenticity, or faithfulness to real-world texts and purposes. Another way that teachers often collaborate with learners is by assisting them to build on their latent understandings of the discipline to explore the ways that communicative intentions are expressed (Swales & Feak, 2004). Teachers also need to collaborate with subject experts. Often the specialist can assist as an informant, providing teachers, or students, with background and insights into the kinds of practices that experts engage in and the texts they use (Johns, 1997). Alternatively, collaboration can involve the specialist acting as a consultant, assisting the teacher to select authentic texts and tasks. More centrally, the specialist can be directly involved through team teaching or by linking a language course with a specialist course by jointly planning tasks and coordinating instruction (e.g., Haas, Smoke, & Hernandez, 1991).

Consciousness-Raising

Much current teaching is strongly focused on rhetorical consciousness-raising, or helping students to become more aware of the language, discourses, and communicative practices in their fields. This means the teacher is closely involved in studying the texts learners will need to use beyond the classroom and finding ways to highlight their features for them. Consciousness-raising is a "top-down" approach to understanding language and encourages us to see grammatical features as "the on-line processing component of discourse and not the set of syntactic building blocks with which discourse is constructed" (Rutherford, 1987, p. 104). Focusing on language is therefore not an end in itself but a means of teaching learners to use language effectively by encouraging them to experience for themselves the effect that grammatical choices have on creating meanings.

This is often novel for students as it seeks to assist them to create, comprehend, and reflect on the ways texts work as discourse rather than on their value as information. It guides learners to explore key lexical, grammatical, and rhetorical features and to use this knowledge to construct their own examples of the genre. Consciousness-raising is therefore designed to produce better writers and speakers rather than simply better texts. Here the teacher's goal is to illuminate the genres that matter to students so that they understand them and use them effectively. Tasks take various forms but generally involve students, often in small groups, analyzing, comparing, and manipulating representative samples of the target text so that features become apparent.

Genre Teaching

Finally, genre pedagogies have become extremely influential in teaching languages for academic purposes. Genres are socially recognized and repeated ways of using language and pedagogies support learners with methods which foreground the meanings and text-types at stake in a situation. These methods offer writers an explicit understanding of how texts in target genres are organized and why they are written or (less often) spoken in the ways they are. To create a well-formed and effective text, students need to know the ways writers structure their purposes in different stages and the lexicogrammatical patterns which typically occur in these stages. The teacher's task is therefore to assist students toward a command of this through an awareness of target genres and an explicit grammar of linguistic choices.

Genre pedagogies assume that writing instruction will be more successful if students are aware of what target discourses look like, but this reproductive element can encourage conformity and prescriptivism (e.g., Freedman, 1994). The dangers of a static, decontextualized pedagogy must be guarded against, but there is nothing *inherently* prescriptive in a genre approach. Teaching practices take a number of forms but usually involve the teacher exploiting relevant and authentic texts through tasks which increase awareness of their purpose and their linguistic and rhetorical features. These include investigating the texts and contexts of students' target situations, encouraging reflection on writing practices, exploiting related genres, and creating mixed-genre portfolios (Paltridge, 2001; Johns, 2002). This makes language learning both more relevant and immediately useful to learners in their studies. More importantly, however, the provision of a rhetorical understanding of texts and a metalanguage to analyze them shifts instruction from the implicit and exploratory to a conscious manipulation of language and choice. It allows students to see texts as artifacts that can be used, modified, questioned, compared, and deconstructed, thus making them easier to create while revealing the assumptions and ideologies that underlie them (Christie, 1987).

Conclusion

Space limitations prevent a fuller coverage, but I have highlighted some key issues in teaching language for academic purposes and pointed to the fact that teachers have become researchers of the genres and communicative practices of their students' target situations and of their own classrooms to discover the ways they learn.

Teaching Language for Peace

PATRICIA FRIEDRICH

As has happened with other transdisciplinary and international concerns, the study of peace is now addressed by many different scholars in an equally diverse number of realms of expertise. This preoccupation is in many ways a reflection of the manner in which globalization and the flow of people, ideas, and products around the world have created not only excitement and new possibilities but also challenges for understanding among human beings. The disciplines interested in peace range from education to psychology, from political science to economics, and from the medical fields to studies in sustainability. The majority of these disciplines now pursue peace studies as a collaborative endeavor among several areas of knowledge, and many scholars work aided by the framework first established by Galtung (1964), according to which both negative peace (i.e., the absence of war) and positive peace (i.e., the building of fair social institutions) need to be addressed for comprehensive peace to result. In sum, peace studies is transdisciplinary in its very conceptualization and therefore open to a variety of creative endeavors by members of different linguistic communities.

It seems intuitive then to expect that applied linguistics, as a field of study that deals with one of the vital elements of human experience—language—would follow suit and contribute to this important multidisciplinary discussion on peace and the ways to achieve it. While there are many ways for applied linguists to address peace, the framework proposed by Gomes de Matos (2000, 2006; also in Friedrich, 2007) covers three important realms that can be conceptualized and addressed in the language classroom: peace through language, peace linguistics, and peace sociolinguistics.

The first of these elements is education about peace through language. In this case, language is a vehicle for the communication of pedagogies, practices, and policies that contribute to peace. Within peace education, scholars, teachers, and students find ways to more easily design and implement a curriculum of peace that addresses issues such as preservation, conflict avoidance, and minority rights among others. A teacher can, for example, teach through the use of a text that discusses access to water or other vital resources, or have students write a newsletter about peace initiatives. As with all other aspects of education, language figures as an important tool for the transmission of knowledge, exchange of ideas, and maintenance of sound institutional practices; without language, education simply could not be.

The second element, in which language is both the vehicle and the central theme, is the realm of cross-cultural and peaceful communications. In that case, cross-cultural differences in language use, variation in rhetorical styles, the language of diplomacy, and also individual ways of using language non-threateningly are addressed. For example, within this realm, scholars can investigate and teachers can teach ways to promote successful language use that fosters understanding between speakers of different tongues despite their potentially different beliefs and values. They can help different specialized fields revamp their jargon so as to eliminate language that is demeaning to one or another group (e.g., women, ethnic minorities, and so forth). In sum, this realm is concerned with the more directly linguistic aspects of peace building and conflict avoidance—both their investigation and then the teaching of such findings to different stakeholders. In the classroom, teachers engaged

2 TEACHING LANGUAGE FOR PEACE

in peace linguistics will, for example, discuss linguistics terms that foster collaboration as opposed to those that might lead to communication breakdowns, or they might survey what terms in the media can heighten a sense of insecurity and fear. This realm is important because it demonstrates to learners that our linguistic choices matter and that by being conscientious users of language, we can cause a positive impact in the world.

Lastly, the third element contextualizes the first two by adding to the teaching of peace macro-level elements that challenge the sociolinguistic realization of peace (i.e., its achievement in societal structures influenced by politics, economics, attitudes, and other dynamic forces). Within this realm one goal is to find ways in which the politics of language complicate the establishment of peace-related practices, and ways in which these political aspects can be navigated successfully. For example, within peace sociolinguistics, scholars might investigate and teachers might discuss which language dynamics are contributing to linguistic homogenization or what linguistic rights are not being upheld within a given society. As might be expected, this domain will raise awareness of the forces working with (and sometimes against) language as well as the ways in which policy, education, and activism can help alleviate their impact when such impact is detrimental. This is also the realm in which large frameworks are developed and communicated to interested parties.

Within applied linguistics, many approaches and related subfields can and have been actively involved in either peace education through language, linguistic education, or sociolinguistic education. For example, Osborn (2000) has addressed peace in the foreign language classroom and the relationship between language teaching and social justice (Osborn, 2006). Birch (2009) has written about the role of the English teacher in civil society. Critical applied linguistics (Pennycook, 1994, 2001), on the other hand, brings to light the ways in which power plays a significant role in language dynamics and thus contributes to linguistic imbalances that in turn result in conflict. World Englishes (Kachru, 1986), or the study of English varieties around the world (and their cultures and contexts), has contributed significantly to an understanding of attitudes toward language as well as the importance of respecting and embracing linguistic diversity. Studies in language ecology (Nettle & Romaine, 2000) have highlighted through their ecological metaphor the importance of balance, documentation, education, and sound policy making when it comes to ensuring the survival of languages. Studies in linguistic rights (Skutnabb-Kangas, 2000) have demonstrated that language does not fall outside the realm of human rights but rather plays a significant role in guaranteeing inclusion, access to education, and knowledge and respect for linguistic heritage. Finally, a new paradigm called “nonkilling linguistics” (Friedrich & Gomes de Matos, 2009) has in innovative and bold ways started to highlight the contributions that linguistics (alongside mathematics, physics, engineering, and other areas of human knowledge) can make to a world without violence and killing.

Much remains to be done, however, when it comes to unveiling the intricate and complex connection between language and peace. While individual scholars have certainly addressed that relationship in their scholarship (Canagarajah, 1999; Crystal, 2004), peace linguistics (Gomes de Matos, 2000, 2006) and peace sociolinguistics (Friedrich, 2007) are only now starting to morph into recognizable (trans)disciplinary orientations. However, a growing interest in peace studies in general, as represented by blossoming programs in many universities around the world and by the availability of many more peace-related jobs in government, nongovernmental organizations, the private sector, and education, will possibly mean a boost in peace-language initiatives and studies as well.

Teaching Language-Learning Strategies

JOAN RUBIN

Introduction

Learning strategies, considered inherent to the act of learning, are what students do when trying to learn and address their learning problems. Research over the past thirty years increasingly confirms that helping language learners to use learning strategies effectively results in increased language proficiency and learner motivation (see Hassan et al., 2005, for the best review of this topic). Continuing investigation has outlined effective instructional strategies for promoting learning of these strategies (Brown & Palincsar, 1982; Coyle, 2007; Graham & Macaro, 2007, 2008; Harris, 2007). In addition, language teacher educators are now identifying the most effective practices to develop teachers' ability to incorporate learner strategies into their language curriculum.

Types of Learning Strategies and the Learner Self-Management Model

More than three decades of research has led to the identification of specific learning strategies adopted by language learners of a range of ages and learning styles (both expert and novice) studying a variety of languages. Several kinds of strategies have been identified: cognitive, metacognitive, and socioaffective. Research (Chamot, 2005; Vandergrift & Tafaghodtari, 2010) has determined that successful language learners control their learning by using metacognitive strategies (i.e., thinking about learning) and making decisions about what to do.

To understand the relationship among these different strategies Rubin (2005) proposed the learner self-management model, based on Butler's (1997) discussion of learner self-regulation as "The ability to deploy procedures and to access knowledge and beliefs in order to accomplish learning goals in a *dynamically* changing environment" (p. 37, italics in the original). Rubin defines *procedures* as the actions learners take to manage their learning by planning (e.g., setting goals, criteria/evidence, a time line; task analysis; creating an action plan), monitoring/noticing, evaluating, problem solving, and implementing problem solutions. Task analysis consists of task purpose (why you want to reach your goal), task classification (what you know about the task) and task demands (how to proceed based on your task classification). Rubin observed that in order to select appropriate cognitive and socioaffective strategies, learners need to base the selection on their task classification.

Adapting Wenden's (1995) definition, Rubin (2005) further defined *knowledge and beliefs* as: task knowledge, person knowledge, strategy knowledge, background knowledge, and beliefs. She then underlined the critical interaction between procedures (strategies to manage learning) and knowledge (information needed for learners to manage their learning).

Cohen (1998, cited in Manchón, 2008, p. 4) provides the most consistent rationale for teaching learning strategies.

2 TEACHING LANGUAGE-LEARNING STRATEGIES

The strategy training movement is predicated on the assumption that if learners are conscious about and become responsible for the selection, use, and evaluation of their learning strategies, they will become more successful language learners . . . In other words, the ultimate goal of strategy training is to empower students by allowing them to take control of the learning process.

Learning involves getting, storing, retrieving, and using information. As such, many cognitive learning strategies are similar to processes identified by other second language acquisition researchers: awareness, attention, hypothesis formation and testing, and practicing. Memory plays a critical role in storing and retrieving; a range of memory strategies can enhance this process. Motivation (Dörnyei, 2001) has been identified as another critical element in the learning process. Pintrich (1999) defined three aspects of motivation: self-efficacy (the belief in one's ability to accomplish tasks), task value (the belief that the task is worth doing), and goal orientation toward learning. If learners are able to manage their learning, greater self-efficacy results.

Characteristics of Learning Strategy Instruction

According to Macaro (2001), "Strategy training is a gradual, recursive, and longitudinal process" (p. 266). Consequently, those interested in promoting strategy instruction should not expect a quick fix, but rather an organized, well-informed endeavor to help learners move toward the goal of self-management. Other important characteristics of learning strategy instruction include that it be contextualized, scaffolded, explicit, with choice, with control, and relevant.

Contextualization

Contextualization means that strategies are taught as part of a language lesson, since the purpose of teaching learning strategies is to enable learners to more easily attain a specific learning goal and accomplish a task. Hence, it is neither effective nor efficient to teach strategies in the absence of goals. The teaching of self-management (including the knowledge needed to use procedures) and the product (i.e., the language) must be integrated since both are interconnected aspects of learning.

Scaffolding

Scaffolding is another critical element in teaching learning strategies. It involves the teacher providing just the right amount of support to enable learners to progress. As learners gain control of their use of strategies, teachers can fade the scaffolding and shift more responsibility for learning to the students. Examples of scaffolding include modeling strategy use, explaining what, why, when, and how a strategy can be used, and providing examples. Fading includes providing just a hint or a prompt. The advantage of scaffolding is that it can be individualized and given "just in time," leading to less learner frustration.

Explicitness

In a classic study, Brown and Palincsar (1982) provided three types of instruction: blind, informed, and controlled. In the blind mode, learners were given an exercise without any explanation of how to perform it; in the informed mode, learners were presented with a strategy, its name, and why it was useful; and in the controlled mode, learners were not only told the name of the strategy and why it was useful but also when it might not be useful. The study found that informed learners outperformed blind learners, and controlled learners did best, illustrating the importance of explicit strategy instruction.

Choice

An important factor in motivating learners and developing their ability to self-manage is giving learners choices about the materials they use to practice, the goals they set for themselves (i.e., what to focus on), their purpose in doing a task (i.e., why they want to focus on a goal), and how they want to go about working on a task. Chamot and Genovese (2009) found that giving students choice of materials increased their motivation.

Control

Strengthening learners' control over their learning is the ultimate goal of strategy instruction. Such instruction includes development of procedures along with enhancing knowledge and clarification of beliefs. Pintrich (2000, cited in Manchón, 2008) observed that it is especially important for learners to set their own goals if they are to achieve control of their learning. Rubin (2005) added that not only do they need to set their own goals but also to establish criteria (i.e., observable evidence) for determining whether they have reached their goals and to do task analysis for selection of appropriate strategies. However, consistent with Macaro's (2001) observation about the amount of time strategy instruction takes, Rubin and McCoy (2008) found that multiple practice opportunities are needed for learners to be able to establish criteria consistently.

Relevance

Strategy instruction should be directly related to the problems that learners are seeking to solve. Unless strategy instruction is used to solve specific learning problems, learners will regard it as an additional burden and simply superfluous.

Instructional Sequences

Although there are a number of models for teaching learning strategies (White, Schramm, & Chamot, 2007, p. 112; see also Rubin, Chamot, Harris, & Anderson, 2007, p. 142), common to all these models is a sequence of four steps: (a) *preparation*: teachers raise learner awareness of problems and strategies; (b) *presentation*: teacher models, names, and explains new strategy, suggesting possible benefits—this can help students become more aware of the thinking and learning process; (c) *practice*: teacher provides multiple practice opportunities to help students move toward autonomous use of the strategies through gradual withdrawal of the scaffolding, eventually enabling transfer of strategies to fresh tasks; and (d) *evaluation*: learners use criteria to evaluate effectiveness of strategies and determine whether they addressed their problem (and, if they did not, to consider what other strategies to use).

Regarding the first step of "preparation," Rubin et al. (2007) provide a comparison of several awareness-raising techniques: questionnaires, focus groups, journals, asking a specific question, and reading about the learning process. An additional awareness-raising technique is cold practice followed by a discussion of strategies used and how effective they were. In terms of the second step of "presentation," one of the most effective techniques for modeling is to "think aloud" whereby teachers (or students) say out loud their thoughts about problems encountered while performing an activity. In this way, students can become aware of how the teacher and other learners try to resolve problems. As far as "practice" is concerned, sufficient practice is critical; it can take many forms and, as mentioned earlier, should be integrated with learning an aspect of the language. Lastly, the fourth step of "evaluation" should be based on preestablished criteria that a learner has achieved a goal. Such criteria can be jointly established when learners are beginning

to understand procedures and can be faded when they are more comfortable with the process.

When first introducing learning strategies, especially to beginners, presenting those that are most likely to lead to success will help learners to recognize the value of this endeavor. Many researchers note that strategies which can enhance memory are the most likely candidates. Rubin et al. (2007, p. 159), note that such success will build self-efficacy (i.e., self-confidence), which is an important component of motivation. Further, they note that “learners should themselves directly feel that the knowledge given through strategy intervention is immediately and directly useful to them” (p. 159). Wenden (1987) observes that not all learners react favorably to strategy instruction and that, in particular, expert learners find such instruction a waste of time. However, since this observation was made when the custom was to present strategies one by one, instead of encouraging learners to consider which of several strategies would work for them, this may no longer be the case. Finally, after much consideration, it is agreed that there are no good or bad strategies, rather strategies that are appropriate for a particular learner, for a particular task, or for a particular goal in a particular setting.

More research is needed to confirm the long-term effect of intervention on language proficiency, to clarify how such interventions are affected by academic level, and to determine which instructional sequences are the most effective for addressing individual differences.

Role of Social Context

Research has shown that social context can affect use and acquisition of learning strategies in two ways: (a) the kind of “learning community” that the teacher builds (Takeuchi, Griffiths, & Coyle, 2007); and (b) how the culture of the subject matter influences the strategies selected by a learner (Uhrig, 2004).

Takeuchi et al. (2007) consider the role of the classroom as a learning community, noting that learning has both an individual and a social component. The social component includes scaffolding (by teachers and peers), group work, sharing problem-solving strategies, and socially constructed goals. In addition, scholars of sociocultural theory suggest that agency and power relations can affect learning, either positively or negatively. Uhrig (2004) found that the strategies which a learner uses depend on the demands of a task (e.g., degree of class participation expected, kind of assignments) and that such demands can influence the extent to which a learner needs to work with a social network to solve learning problems.

Challenges in Teaching Strategies

Teachers’ success in promoting the use of learning strategies depends on a number of variables beyond their control. Among these are mandated textbook requirements; high-stakes tests; curricula; class size and configuration; and schedules. When these macrostructures are not aligned in such a way as to facilitate the teaching of learning strategies, it can be more challenging to teach them. Rubin (2010) provides some effective solutions to these difficulties, including strong administrative support and a supportive network of colleagues. Another challenge may be learners’ beliefs and experience about who bears the major responsibility for learning. It can take a lot longer to develop learners’ ability to take control of their learning when they believe that it is the teacher’s responsibility for learning to take place. Finally, it is critical for teachers to be thoroughly grounded in the process of teaching learning strategies; administrators should provide the necessary time and training for this to happen (see Rubin, 2010, for a review of challenges in so doing).

Teaching Adolescent and Adult Language Learners With Limited or Interrupted Formal Schooling

MARTHA BIGELOW

Worldwide, formal schooling is not available to all individuals for reasons ranging from political and social unrest on a large scale to economic necessity among individuals and families. Circumstances causing limited formal schooling also cause international migration. This phenomenon of massive movement of people into economically developed countries explains the appearance of students without formal schooling in language classes and other educational programs. Limited or interrupted formal schooling has serious consequences for adolescents and adults who are learning a language or becoming schooled in a new language.

One of the most important consequences of limited or interrupted formal schooling among this population of language learners is low levels of print literacy skills. It is possible to become print literate outside of school—a family member or sibling could teach an individual to read and write, even during difficult times. However, little or no print literacy is fairly common and is usually the result of limited or dramatically interrupted formal schooling. In the United States, it is estimated that there are about 750,000 adult immigrants who lack print literacy in any language (McHugh, Gelatt, & Fix, 2007). While these adolescents and adult learners are wise and capable in many domains, often including the acquisition of new languages through the oral modes, they have not had the opportunity to learn how to produce and interpret print in the language(s) they speak. This is not to say they do not possess other literacy skills, framed broadly (e.g., the literacies needed to understand poetry genres in the oral mode, the literacies needed to deconstruct the meaning of a piece of art). Students must have the opportunity to acquire the basics of print literacy (e.g., text orientation, notion that print carries meaning), and in many educational settings in the world, students must acquire the basics of *alphabetic* print literacy. The process of becoming literate in an alphabetic language such as English or Arabic involves learning sound–symbol correspondences, blending sounds, word segmentation, and many other skills which typically fall under the broad categories of phonemic awareness and phonics.

With regard to prior literacy, research has shown that learners who have strong mother-tongue literacy can use these skills in a new language (Koda & Zehler, 2008). It is possible to transfer, on a basic level, the notion of the alphabetic principle which includes knowing that there are predictable links between sounds, symbols, and words. Learners without print literacy must acquire these skills. The transfer of literacy skills also makes it possible for educated and highly literate adults to transition to a new workplace or educational system. It is possible to acquire rather quickly new genres of writing, and leverage reading strategies to comprehend text in a new language, when an individual has mastered many genres of writing and is educated at a level typical to their age in their home country.

Many researchers have argued that print literacy, and particularly alphabetic print literacy, changes the way one processes language in the mother tongue (e.g., Petersson, Ingvar, & Reis, 2009), as well as in an additional language (Tarone, Bigelow, & Hansen, 2009). Literacy,

some argue, even alters the way people think, in broad terms (e.g., Ong, 1982). What does the visual codification of language do to the mind? What does it do to how oral language is processed? In their study of corrective oral feedback, Tarone et al. (2009) found that literacy helped language learners accurately repeat a recast (correct reformulation of an error they produced) which focused on the syntax of question formation in English. Recasts which offered corrections on multiple errors were recalled better by participants who were more literate as well. Ong (1982) argues that the type of schooling characteristic of Western societies supports literacies and ways of thinking that are characterized by abstraction, classification, hierarchicalization, and hypothesizing. Adolescents and adults without print literacy have unique instructional needs because of these differences in how they use and process language.

Another consequence of limited or interrupted formal schooling is little knowledge in what we think of as school subjects, framed in ways legitimized by the discourses prevalent in Western academia. An adolescent or adult without formal schooling may have learned how to cure the sick, build a house, raise children, enact a famous folktale, or grow vegetables, but this knowledge cannot be explained in terms of academic subjects such as mathematics, biology, or literature. Knowledge among unschooled adolescents and adults is acquired through observation of and interaction with skilled individuals, not through books, conventional laboratories, or analysis of canonized works. Furthermore, formal schooling supports the acquisition of certain ways of thinking that are idiosyncratic of formal schooling. Consider academic language functions such as describing complex tables, charts, relationships between characters, and writing complex ideas following the conventions of different disciplines (e.g., Zwiers, 2006). Typical ways of learning these skills through classroom tasks, group work, handouts, or Web sites may be other ways in which learners without familiar schooling undergo a mismatch in background experience with same-age peers without interrupted schooling.

The differences in worldview and experience between language learners (and teachers) with and without formal schooling may seem like an abyss (Watson, 2010). On one side of the abyss is indigenous knowledge, orality, traditional ways of transmitting information; and on the other side is highly digitized, literate, and academic ways of being. Some of the implications for teaching involve the recognition of the following principles. First, literacy must be taught (Royer, Abadzi, & Kinda, 2004; Birch, 2007), but taught in ways that are appealing and appropriate to adolescents and adults (Vinogradov & Bigelow, 2010). Second, metalinguistic knowledge, or explicit understandings about how language works as a system, may be helpful in beginning to visualize oral language and better notice certain morphemes or syntactical patterns (Lindberg, 2003; Kurvers, Vallen, & van Hout, 2006). However, this knowledge must build on existing skills and develop as the ability to visualize language develops. Finally, instruction must move from the concrete to the abstract through a scaffolded and culturally relevant curriculum (Klassen, 1991; Farr, 1994; DeCapua & Marshall, 2010).

Teaching Less Commonly Taught Languages

KIMI KONDO-BROWN

Less commonly taught languages (or LCTLs) is a label primarily used in the context of teaching foreign or heritage languages in the United States (USA). It technically refers to any one of the 6,909 known living world languages (see Lewis, 2009) other than English, as well as Spanish, French, and German—the three most commonly taught foreign languages in American schools, colleges, and universities. LCTL enrollment figures and instructional capacity differ considerably across time and place, depending on the demographic, cultural, economical, and political context (e.g., Brown, 2009). As one way to address this diversity, Brecht and Walton (1993) proposed to categorize LCTLs into four subgroups, depending on the total enrollment figures in US postsecondary institutions, which range from as low as a single digit up to thousands: “the principal less commonly taught languages” (i.e., LCTLs generally available in the USA such as Arabic, Japanese, and Russian); “the much less commonly taught languages;” “the least commonly taught languages;” and “the rarely (or never) taught languages.”

Today, overall enrollments in LCTL programs are rapidly expanding at all levels. Although LCTL programs within the K-12 system are still far less numerous than those offered in American higher education, their development in recent years is nonetheless phenomenal. For example, two recent national enrollment surveys, one for K-12 (kindergarten through 12th grade) and the other for colleges, indicate that enrollments in LCTLs such as Arabic and Chinese blossomed in recent years (Furman, Goldberg, & Lusin, 2007; Rhodes & Pufahl, 2009). At the college level, other LCTLs such as Russian, Japanese, Portuguese, and Korean also increased by a large margin, but the increase was not as dramatic as Arabic and Chinese. Due to the expansion of LCTL instruction, the dominance of these commonly taught languages relative to LCTLs is narrowing in US colleges and universities (Furman, Goldberg, & Lusin, 2007). If one wants to discover where LCTLs are taught in American educational institutions, the Center for Advanced Research on Language Acquisition's (CARLA) LCTL project provides one of the largest databases covering the availability of LCTL programs (see <http://www.carla.umn.edu/lctl/db/index.html>). The LCTL project database presently provides information for over 300 languages offered at more than 2,000 educational institutions in the USA.

One reason for the recent expansion in LCTLs is the continuing national demand. The USA needs citizens who can demonstrate ability in LCTLs and expert knowledge of the countries or regions where these languages are spoken (Ryding, 2001). These skills and knowledge are not only necessary for conducting US overseas diplomacy, but also are critical in light of the current political climate and the global economy. Due to the increased national requirement for citizens who are proficient in LCTLs, the USA has expanded federal support for these languages at all levels. In K-12 schools, some of the most important federally funded programs and initiatives include the Foreign Language Assistance Program (FLAP) and STARTALK (<http://startalk.umd.edu>). FLAP is one of the largest federal providers of resources for foreign-language instruction at K-12 schools, and it has been instrumental in promoting LCTL programs in K-12 schools. STARTALK is a National Security Language Initiative (NSLI) program administered by the National Foreign

2 TEACHING LESS COMMONLY TAUGHT LANGUAGES

Language Center at the University of Maryland and is one of the most significant federal initiatives for critical LCTLs, offering teacher development as one of its mandates in addition to outcomes-driven programs across K-16.

At the college and graduate levels, for example, the federal government has funded a number of national flagship programs as part of the National Security Education Program (NSEP) in recent years. These programs are offered for LCTLs which are critical to national security such as Arabic, Chinese, Korean, Persian, and Russian in competitive university foreign-language departments (some are in K-12 schools) and have opened up a very promising avenue for those who are motivated to achieve professional-level proficiencies in these LCTLs. Another example is the Foreign Language and Area Studies (FLAS) fellowship program. The FLAS is one of the largest and most important components of federal support for American graduate students who are working toward advanced language ability in LCTLs. Funded in the late 1950s, the FLAS program goals have gone through many transformations (see McDonnell, Stasz, & Madison, 1983), but federal support for LCTL training has remained a major priority.

Thus, there is considerable national interest in and federal support for promoting LCTLs in order to meet the nation's diplomatic, economic, and security needs. At the same time, federally funded national centers, such as the National Heritage Language Resource Center (<http://nhlrc.ucla.edu/>), promote the teaching of LCTLs as heritage languages. In fact, many learners of LCTLs in American educational institutions are studying these languages as their heritage languages (Lee, 2005). Broadly speaking, heritage languages are any family or ancestral languages spoken by immigrant or indigenous groups. Therefore, heritage students on LCTL courses may be studying the language as their first-learned language, the language used in the home, or as an ancestral language that is no longer spoken in the family or community. In the USA, heritage language instruction in LCTLs is widely available within and outside the formal education system. At present, no comprehensive data are available on the availability of such instruction, but the Heritage Languages in America Web site (www.cal.org/heritage/index.html) provides perhaps the most comprehensive information for heritage language courses available in LCTLs.

To some extent, whether or not the target language is an LCTL, professional foreign-language teachers may employ a set of assumptions or hypotheses about language teaching that draw on second language acquisition and pedagogy research (Walker & McGinnis, 1995). In fact, LCTL materials developers *do* create instructional and assessment materials and pedagogical strategies using the existing second language acquisition theories or curriculum or assessment models (e.g., Johnston & Janus, 2009; also see chapters that deal with LCTLs in Stryker & Leaver, 1997). At the same time, since LCTLs are taught on a relatively limited scale, LCTL teachers may face issues and challenges that other types of language teachers do not have to deal with. For example, it has been a major concern that professional development opportunities as well as instructional and assessment materials are less available to LCTL teachers than they are for teachers of languages in a dominant position (McGinnis, 1994; Johnston & Janus, 2003). Also, standards-based proficiency tests such as the online Standards-Based Measurement of Proficiency (STAMP, see www.avantassessment.com/products/about_stamp.html) developed by the Center for Applied Second Language Studies (CASLS) are currently only available for a limited number of LCTLs.

In addition, although language teachers of any type may have to cope with individual differences in proficiency levels, learning needs, and interests within the same classroom, the degree of variation may be considerably wider in LCTL classes. Many LCTL classes are mixed-ability courses where teachers are trying to meet the needs and interests of students from various language backgrounds in terms of heritage language backgrounds, class standing [graduate and undergraduate], etc. (see Ilieva, 2008). Projects that specifically address this issue are emerging. For example, the Center for Advanced Language

Proficiency Education and Research (CALPER) project, entitled Teaching Domestic and Heritage Language Learners in LCTL Courses (<http://calper.la.psu.edu/heritage.php>), has developed multimedia professional development materials for LCTL teachers who teach in mixed-level courses where heritage and foreign-language students are enrolled in the same classrooms. Furthermore, the widely cited US Foreign Service Institute's empirical data suggest that, depending on how close the target language is to English, vastly different numbers of instructional contact hours may be necessary for students to achieve the desired target proficiency level (Liskin-Gasparro, 1982). Languages belonging to the more or most difficult-to-learn categories are generally LCTLs. Such information suggests further challenges that LCTL teachers may face.

There are notable federally funded centers and organizations that provide support for LCTL teachers and learners who often lack suitable materials. For example, the National Council of Less Commonly Taught Languages (NCOLCTL) is a national organization that aims to promote instruction and research on LCTLs and LCTL teaching. NCOLCTL is committed to enhancing advocacy for LCTLs and LCTL teachers; it hosts an annual conference and publishes a peer-reviewed journal (for more information, visit <http://www.ncolctl.org/jncolctl-links>). NCOLCTL and the Language Institute at the University of Wisconsin-Madison have recently developed three new standards-based online courses on teaching LCTLs at the postsecondary level (for information visit <http://www.ncolctl.org/resources/links/online-teaching-course>).

The LCTL project at CARLA mentioned above also provides resources for teaching and learning LCTLs. The center's Web site provides a link to instructional materials available in a variety of LCTLs (www.carla.umn.edu/lctl/materials/index.html). The project actively produces LCTL-related publications and hosts professional workshops that help LCTL teachers obtain practical tools and hands-on experience in developing instructional materials specifically designed for the target LCTL learners. The National Foreign Resource Center (NFLRC) at the University of Hawai'i also publishes a variety of research findings and instructional materials for LCTLs. For example, one of the NFLRC publications by Spreen (2002) offers technology-based instruction options for LCTLs (the entire document is available at <http://www.nflrc.hawaii.edu/networks/TR25/>). Other online resource projects such as the Webliography of LCTLs hosted by the federal Interagency Language Roundtable (www.govtirl.org/web_lctl/index.htm) and the Language Materials Project (www.lmp.ucla.edu/) hosted by the University of California, Los Angeles provide rich resources for LCTL teachers by creating numerous links to online Internet materials for a variety of LCTLs.

Thus, partly due to the national mandate to enhance US citizens' ability in LCTLs, enrollments in LCTLs in the USA have shown remarkable growth in recent years. Through advanced technologies, conferences, and workshops, national resource centers and organizations have played a vital role in providing instructional materials and professional training to LCTL teachers across the nation. Clearly, federal support for these centers and organizations will continue to be critical to the future development of LCTL programs in US educational institutions.

Teaching Listening

LARRY VANDERGRIFT

Listening is a critical part of everyday life; yet it is the weakest language skill for many second and foreign-language (L2) learners. This may be because listening is a particularly complex cognitive skill that must be carried out automatically in real time. Listeners must process speech which may be characterized by phonological irregularities (e.g., accent, reduced forms); simultaneously listen to new speech delivered at a speed over which they have no control; segment this sound stream into meaningful units; and, interpret what the speaker means. This is no small feat and L2 learners are rarely given any systematic support to learn to control these processes.

This entry will present a brief overview of the processes involved in L2 listening, current research on the teaching of L2 listening, and a pedagogical sequence for sensitizing language learners to the processes underlying listening. I argue that teaching L2 learners how to listen can help them better control these listening processes and become more successful listeners outside the classroom.

L2 Listening Processes

Listening comprehension is an active process of meaning construction in which listeners, based on their purpose for listening, attend to and process aural and relevant visual input, automatically in real time, in order to understand what is unequivocally stated and to make all necessary inferences implied in the message (Buck, 2001). In order to do this, listeners engage in bottom-up and top-down processing, using different knowledge sources to interpret the intention of the speaker. Bottom-up processing involves segmenting the sound stream into meaningful units. When listeners work in a bottom-up manner, they construct meaning by gradually combining increasingly larger units of meaning from phoneme-level up to discourse-level features. Top-down processing, on the other hand, involves the application of context and prior knowledge to build a conceptual framework to interpret the meaning of what is understood. Listeners use initial cues (linguistic, paralinguistic, or visual) in the text or the context of the listening event to activate a conceptual framework for interpreting the message. The different knowledge sources listeners can apply to this interpretation process include experiential, cultural, text, linguistic, and pragmatic knowledge. Linguistic knowledge gleaned from the decoding process and world knowledge applied to the interpretation process interact in parallel fashion as listeners create a mental representation of what they have heard (Hulstijn, 2003).

Although successful listening comprehension involves a judicious interplay between the two processes, the degree to which listeners use one process more than the other will depend on the purpose for listening, learner characteristics (e.g., age, language proficiency), and the context of the listening event. A listener who needs to verify a specific detail, for example, will engage in more bottom-up processing than a listener who is interested in obtaining the gist of what happened. Successful listening depends on the degree to which listeners can coordinate these processes efficiently. First language (L1) listeners do this automatically, with little conscious attention to individual words. L2 listeners, on the other hand, usually have more limited language knowledge; therefore, not everything that they

hear may be processed as efficiently. Either comprehension breaks down or they use compensatory strategies, contextual cues, and any other relevant information available to them to guess at what they did not understand.

Anderson's Cognitive Model of Listening Comprehension

A useful cognitive model for gaining greater insight into how listeners construct meaning while bottom-up and top-down processing occurs is Anderson's (1995) differentiation of listening comprehension into three interconnected phases: perceptual processing (perception), parsing, and utilization. Although they may suggest a sequence, the listening phases in this model have a two-way relationship with each other, reflecting the interactive and integrated nature of the processes.

During the perception phase, listeners recognize sound categories of the language, pauses, and intonation emphases, and hold these in working memory. Perception involves bottom-up processing. Listeners encode incoming speech by (1) paying attention to the text to the exclusion of other sounds in the environment; (2) noting similarities, pauses, and acoustic emphases in the sound stream relevant to a particular language; and then (3) grouping these according to the categories of the identified language. This is the initial stage in the word segmentation process.

During the parsing phase (also bottom-up processing), listeners segment what was retained in working memory and begin to activate potential words. Listeners retrieve word candidates from long-term memory (LTM) based on different cues; however, meaning is often the principal cue in segmentation. As language proficiency develops, listeners activate successful word candidates (for the context) more quickly and hold meaning in increasingly larger chunks of information.

Finally, in the utilization phase, which involves top-down processing, listeners relate the resulting meaningful units to information sources in LTM to interpret the intended or implied meanings. An important characteristic of this phase is that listeners use information from outside the linguistic input to interpret what they have retained. Using linguistic, world, and pragmatic knowledge (different types of knowledge stored as schemas in LTM), listeners elaborate on the new information and monitor it for congruency with both their previous knowledge and their developing interpretation of the text as often as necessary within the time available. Listeners generate a conceptual framework in which to slot the emerging meaning of the text or utterance and to interpret beyond the literal meaning of the input. Listening comprehension then becomes a process of matching what is heard with expectations based on prior knowledge and making contextually informed elaborations in order to infer the speaker's meaning.

Regulation of these cognitive processes is facilitated by the listener's metacognitive knowledge about L2 listening (Goh, 2008); that is, knowledge and beliefs about the task-, person-, and strategy-related factors that interact during any cognitive activity. Application of metacognitive knowledge is a mental process shared by successful learners; in fact, metacognition accounts for a relatively high percentage of variance in learner performance (Veenman, Van Hout-Walters, & Afflerbach, 2006). There is extensive evidence that learners' metacognition can directly affect the process and the outcome of their learning (Zimmerman & Schunk, 2001), that it is positively linked to motivation and self-efficacy (Paris & Winograd, 1990), and that it can help learners regulate their comprehension (Pressley, 2002). Vandergrift, Goh, Mareschal, and Tafaghodtari (2006) observed that about 13% of variance in listening achievement could be explained by metacognition. Furthermore, research on listening strategy use (e.g., Vandergrift, 2003a) has revealed that successful L2 listening involves a skillful orchestration of metacognitive and cognitive strategies to regulate listening processes and achieve comprehension.

Teaching Listening: Bottom-Up and Top-Down Approaches

Teaching L2 listening typically focuses on the product: the correct answer. As a result, research on improving L2 listening has focused primarily on experimental studies to improve listening test scores. While this body of research has been useful to demonstrate that providing L2 listeners with contextual information can improve comprehension, there has been little interest in determining *how* listeners use this information to improve comprehension or what they do when comprehension fails. An exclusive focus on the product, often associated with testing, creates a high level of anxiety and does not help listeners learn how the comprehension process works. This narrow focus calls for a more enlarged pedagogy of listening that not only helps improve comprehension ability but also helps listeners deepen their understanding of the demands and processes of L2 listening and better manage their comprehension efforts. The following sections will examine some bottom-up and top-down approaches to L2 listening instruction and then present a more holistic, integrated model of listening instruction that can raise greater learner awareness of the processes involved in L2 listening.

Bottom-Up Approaches

The bottom-up dimension of listening involves decoding the sound stream. Research shows that when listeners attempt to segment the speech stream, they are confronted with three basic challenges: processing problems (an inability to rapidly locate word boundaries), text problems (inadequate L2 vocabulary knowledge), and intrusion problems (involuntarily applying L1 segmentation procedures) (Cross, 2009a). Since word segmentation remains particularly difficult for lower-proficiency listeners, an important skill to develop in L2 listening instruction is rapid word recognition.

There is very little research, however, on the types of activities that help learners automatize their ability to recognize words in speech. In terms of listening exercises, teachers can engage students in analysis of parts of the text transcript, in dictation, or in analogy exercises, within the context of a listening task (e.g., post-listening phase), so that these exercises are part of meaningful language use (Goh, 2002). Field (2008) provides a framework of remedial activities to rectify listening problems. To develop automaticity in word recognition, Hulstijn (2001) recommends listening to “i-1 level” texts so that listeners can listen for slight discrepancies between the aural and written forms of the text. Dictogloss can help L2 listeners notice differences between their reconstructed text and a written transcription of the original (Wilson, 2003) and gain greater insight into their comprehension errors. Although these exercises show promise for the development of perception skills, they do not yet have empirical support.

Technology can also be used to develop perception skills. Repeated audio delivery, slowed audio text delivery, and digitized audio text transcripts can be particularly helpful for segmenting or analyzing the individual components of the speech stream. Videos with multilingual sound tracks and captions offer L2 listeners the choice of captions in L1 or L2 to facilitate comprehension. Although L2 captions can facilitate comprehension, long-term effects of learning, in terms of listening improvement and vocabulary learning, still need to be determined (Jones, 2006). Captions may facilitate immediate comprehension; however, their usefulness for learning to listen is still a matter of debate; students will not *learn* how to listen if they become dependent on reading captions to understand listening texts (Vandergrift, 2004). In order for students to learn how to listen, they should resort to these tools only after they have first tried to understand the message using real-life listening strategies such as prediction and monitoring.

Top-Down Approaches

The top-down approach to listening involves the application of prior knowledge (world, linguistic, textual, pragmatic, and cultural) as well as metacognitive knowledge about listening to the comprehension process. The role of world knowledge in successful L2 listening comprehension has long been established. Research into pre-listening activities has documented positive effects on listening performance for visuals, advance organizers, and questions. Provided with a context, listeners can activate prior knowledge and develop a conceptual framework for inferencing what is not understood. Although world knowledge is important for facilitating comprehension, it can also be misleading when used inflexibly. Listener use of prior knowledge can lead to inaccurate comprehension when it is not supported by corroborating evidence as the text unfolds (Macaro, Vanderplank, & Graham, 2005). This underscores the importance of flexibility in the comprehension process; listeners must continually monitor their comprehension.

Research on the systematic development of metacognition, that is, listeners' awareness of the L2 listening process and their ability to regulate the underlying processes (prediction, monitoring, evaluating, and problem solving), is a relatively recent development. Listening diaries and questionnaires (Goh, 2002) and process-based discussions (Vandergrift, 2003b; Goh & Taib, 2006) can provide learners and instructors with important information concerning L2 listeners' degree of awareness of listening problems and how to rectify them. The Metacognitive Awareness Listening Questionnaire (MALQ), a short self-report instrument grounded in listening theory, can raise learner awareness of the processes underlying L2 listening or help language instructors diagnose student listening problems (Vandergrift et al., 2006). Research shows that L2 listeners of different ages and backgrounds, engaged in process-based listening tasks that raise awareness of metacognitive processes underlying listening, have reported increased motivation, confidence, and strategy knowledge (Vandergrift, 2003b; Goh & Taib, 2006).

Research evidence for the long-term benefits of strategy instruction remains inconclusive (Field, 2008). Evidence that skilled listeners appear to use strategies in an interconnected fashion (e.g., Vandergrift, 2003a) may explain why instruction in individual strategies does not appear to lead to overall listening improvement (Field, 2008). A recent study by Cross (2009b) found no differences between a group receiving explicit strategy instruction and a comparable group receiving no explicit instruction. Cross hypothesizes that the significant improvement of both groups might be attributed to the use of a task-based pedagogical sequence reflecting real-life listening similar to the pedagogical sequence advocated by Vandergrift (2004, 2007). On the other hand, Graham and Macaro (2008) recently demonstrated that both a high- and a low-scaffolded group out-performed a control group at the end of the study and six months later. However, the researchers attribute improved listening performance to the "clustering of strategies" and the task-specific and learner-centered characteristics of the intervention.

Integrating Bottom-Up and Top-Down Approaches: A Pedagogical Sequence for Teaching Listening

Until recently, little attention has been given to systematic practice in L2 listening. Systematic practice with a sequential repertoire of strategies has already been documented in L2 reading, where there is general consensus that this kind of instruction is more effective than individual strategy instruction for teaching comprehension skills (Grabe, 2004). In the case of L2 listening, however, this approach to instruction is just beginning to emerge. Table 1 outlines a task-based, pedagogical sequence that leads listeners through the processes involved in real-life listening, developing both the top-down and bottom-up

Table 1 Pedagogical sequence for teaching L2 listening (adapted from Vandergrift, 2004, 2007)

<i>Pedagogical stages</i>	<i>Metacognitive processes and strategies</i>
<i>Pre-listening: planning/predicting stage</i>	
1. After students have been informed of the topic and text type, they predict the types of information and possible words they may hear.	1. Planning and directed attention
<i>First listen: first verification stage</i>	
2. Students verify their initial hypotheses, correct as required, and note additional information understood.	2. Selective attention and monitoring
3. Students compare what they have understood/ written with a partner, modify as required, establish what still needs resolution, and decide on the important details that still require special attention.	3. Monitoring, planning and selective attention
<i>Second listen: second verification stage</i>	
4. Students verify points of earlier disagreement, make corrections, and write down additional details understood.	4. Selective attention, monitoring and problem solving
5. Class discussion in which all class members contribute to the reconstruction of the text's main points and most pertinent details, interspersed with reflections on how students arrived at the meaning of certain words or parts of the text.	5. Monitoring and problem solving
<i>Third listen: final verification stage</i>	
6. Students listen specifically for the information revealed in the class discussion which they were not able to decipher earlier, or compare all or selected sections of the aural form of the text with a transcript of the text, or do both.	6. Selective attention, monitoring, and problem solving
<i>Reflection and goal-setting stage</i>	
7. Based on the earlier discussion of strategies used to compensate for what was not understood, students write goals for the next listening activity.	7. Evaluation and planning

dimensions of listening as well as metacognitive awareness of the cognitive processes underlying listening (see Vandergrift, 2004). Through an orchestrated use of hypothesis formation (planning) and verification (monitoring), with the judicious application of prior knowledge to compensate for gaps in understanding (problem solving), along with opportunities for reflection (evaluation), listeners can acquire implicit knowledge about listening processes and achieve greater listening success.

This pedagogical sequence has strong theoretical support, in that it closely parallels research findings demonstrating implicit learning through task performance (Johnston & Doughty, 2006). It also finds empirical support in some recent studies. Over the period of one semester, intermediate-level learners of French who were guided through this process approach to listening significantly out-performed learners in the control group (Vandergrift & Tafaghodtari, 2010). To control for the variables, both groups were taught by the same

instructor using the same texts. Not only did the experimental group significantly outperform their control group peers but, more importantly, the less-skilled listeners in the experimental group made greater gains than their more-skilled peers, demonstrating that less-skilled listeners, in particular, can benefit from this kind of guided listening practice. Cross (2009c) investigated the development of metacognition through the same pedagogical sequence with more advanced Japanese learners of English. Listeners demonstrated the usefulness of collaborative dialogue in mediating metacognitive development; in particular, strategy awareness, comprehension awareness, and text awareness. Finally, using this same sequence with low-proficiency and high-proficiency civil servants in intensive language training, Mareschal (2007) documented, from triangulated data, how learners were better able to regulate their listening processes as a result of the pedagogical intervention, particularly the low-proficiency group. Systematically leading language learners through the process of listening as part of regular listening activities is beneficial because it encourages learners to practice some of the metacognitive processes underlying real-life listening.

Fundamental to this pedagogical sequence is repeated and systematic exposure to the same sequence of metacognitive processes used by skilled listeners. Although the teacher will initially play a greater role, scaffolding should be gradually removed so that students do the work themselves and the process becomes automatic. Furthermore, matching all or parts of the aural text with the written text helps listeners develop awareness of form–meaning relationships and word recognition skills. It is important, however, that the latter step takes place only *after* listeners have engaged in the cognitive processes underlying comprehension, using only cues natural to real-life listening.

Buck (1995) recommends that, in order to become successful listeners, language learners need lots of listening practice. He suggests that this can be facilitated if teachers understand the underlying cognitive processes, sensitize students to the intricacies of listening, and provide “optimum” listening practice. The pedagogical sequence presented in this entry can help L2 learners by sensitizing them to the cognitive processes underlying listening, helping them regulate these processes, and thereby improving their listening ability.

Teaching Literacy

EVE GREGORY

There can be few issues as contentious as the teaching of literacy in Western societies. Literacy (or the lack of it) has been seen as responsible for a country's economic success or failure, its increased or decreased crime rate, as well as the level of civilization or morality of its citizens. Little wonder, therefore, that the way in which literacy is formally taught has made numerous U-turns over the past century. No sooner has one approach established itself than evidence is found to suggest that it fails some children. Consequently, the hunt is always on for the foolproof approach, whereby all children will learn to command the skill of reading and writing proficiently by the end of their primary schooling. Yet it always remains elusive. It is against this backdrop that we need to understand the contrasting beliefs as to how literacy is learned and, consequently, how it should be taught. What follows is a brief résumé of these beliefs and the corresponding approaches to teaching both reading and writing in Western societies during the 20th and into the 21st century.

The Teaching of Reading

The relationship between reading, language, and the mind has long been a question of debate. In his revolutionary book *The Psychology and Pedagogy of Reading*, published in New York in 1908, Edward Huey claimed that reading is "a highly complex task which involves very many of the most intimate workings of the mind" (p. 6). However, since then there have been contradictory ideas on exactly how complex a task reading actually is and how exactly these "workings of the mind" take place. The traditional debate, which took place throughout the 20th century, sometimes referred to as "the great debate" by Chall (1979) and explained fully by Adams (1995), was between those supporting "bottom-up" and those upholding "top-down" processes as to how children learn to read. Such specialist jargon can sometimes be confusing, but it is important to understand these terms since they reflect theories that have been influential in informing reading tuition throughout the 20th and into the 21st century. At its simplest, the "bottom-up" theory claims that learning to read proceeds from the particular to the general: from the smallest unit of meaning (individual sound or *phoneme*) to the largest, or knowledge of the word (*semantic knowledge*) and knowledge of the structure of language (*syntactic knowledge*).

Those supporting the "bottom-up" process of reading maintain that learning requires a reconstruction of the sound forms of a word on the basis of a graphic representation, whereby understanding arises as a result of a correct re-creation of the sound form of words. Early reading tuition based on the "bottom-up" theory will stress the need to teach children to match phonemes (sounds) to *graphemes* (symbols) which are gradually built up into *lexis* (words) and larger units of meaning. This approach to teaching reading is sometimes referred to simply as taking a "phonic" approach to beginning reading. In its extreme form, individual sounds form the starting point, whereby a child only gradually learns to blend these into syllables and words. This is often called *synthetic phonics*. However, whole words may be broken up into similar sound patterns (e.g., f-ork, p-ork) which is often referred to as *analytic phonics*.

An equally strong view informing the teaching of reading comes from educationalists for whom “top-down” approaches are as important as “bottom-up,” for whom phonics teaching is only one strategy among others, and for whom “meaning” and “decoding” are intrinsically linked. These researchers and practitioners, from a number of countries in the Western world, see learning to read as an interaction between information from four sources: the graphophonic (sound to symbol correspondence), the lexical (recognition of whole words), the syntactic (understanding and predicting the grammatical structure of a sentence), and the semantic (understanding the meaning or the sense relating to the culture or text). These beliefs translate into approaches to teaching reading that offer children whole and meaningful texts (often referred to as “whole language” in the USA or “language experience” in the UK) whereby phonics will principally be used as a second step to dissect words that are meaningful and familiar to children. In other words, children start from *meaning* rather than *sound* as in the “bottom-up” approach.

The Teaching of Writing

The teaching of writing has often taken a back seat in contrast with reading tuition. This is possibly because it has traditionally been recognized as a skill reserved for the more powerful members of society rather than a skill accessible to all. The writing practices of ordinary people are often rendered invisible (Street & Street, 1991). Kress (1982, p. 34) refers to “productive” and “reproductive” writing, whereby productive writing goes together with high levels of education and economic or political power; reproductive writing refers to the routinized writing of scribes, secretaries, and schoolchildren. The distinction made between *content* (the creative act of composing) and *form* (spelling and grammatical accuracy), or “composing” and “scribing” (Hendricks, 2007), is likewise reflected in the teaching approaches in formal educational settings. If children are treated as “authors” (having “authority” over their writing), teachers will focus more on the content than the form. If, on the other hand, they are seen as “scribes,” emphasis will rather be placed upon spelling and grammatical accuracy rather than the creative content itself.

As with the teaching of reading, there have been contrasting views on how best to promote the art of writing in school. During the 1970s and 1980s there was a strong swing to viewing children as emerging “authors,” learning through a process of constructing meaning into text. This approach, often known as the “process approach” to teaching writing, shifts the focus from a completed text to learning the processes required for writing. Graves (1983) divides the writing process into several stages, beginning with initial discussion and drafting, and moving on to conferencing, revising, editing, and publishing, where the child chooses the topics and is guided by the teacher. The process approach was criticized by others who saw the danger in children (a) neglecting the “form” (spelling and grammar) necessary for their work to be understood, and (b) neglecting a full range of genres (purposes of writing, such as procedures, descriptions, reports, explanations, arguments, and different types of narrative).

From this, therefore, developed the functional or genre approach to teaching writing, whereby teachers use cyclical, systematic, and explicit instruction delineating four stages: (a) introducing a text model of the genre, (b) analyzing the structure and grammatical features of the genre with the learners, (c) jointly producing a text of the same genre with the learners, (d) letting the learners write the genre independently (Martin, 1985). Genre theorists argue that factual writing can give access to genres of power and enable a critical engagement with social reality in ways that other forms of writing do not. Thus the dispute in ways of teaching writing has centered largely on (a) the importance of “content” in relation to “form” (i.e., the substance and content of the writing itself vis-à-vis the grammar,

spelling, and punctuation in which it is expressed), and (b) the importance of expressive writing (i.e., writing emanating from the “self,” one’s thoughts and feelings) as opposed to factual or other types of writing.

Sociocultural Ideas on Literacy in Practice

More recently, a third view has become influential in the teaching of literacy in formal settings: the “social” or “sociocultural approach” to reading. Proponents stress the importance of understanding all forms of literacy as integral parts of *cultural practices* (Heath, 1983; Street, 1984; see also Barton & Hamilton, 1998; Gregory & Williams, 2000). In other words, in their outside school lives, children become members of different cultural or social groups demanding knowledge of different types of literacies (e.g., the literacy of a church, mosque, or temple, scout or other youth group) which should be recognized and acknowledged by the school.

Such acknowledgment also means that teachers recognize the different mediators or informal “teachers” of literacy in children’s lives, such as parents, siblings, grandparents, peers, and other members of the community, as well as the different reading materials that children might be using in these contexts (Gregory, 2008). These studies see reading and writing in terms of “literacies” rather than “literacy” (Gee, 1996) and stress the importance of recognizing that literacy learning is multimodal, often involving new technologies as well as rituals, objects, song and dance, and so forth (Gregory, Choudhury, Ilankuberan, Kwapong, & Woodham, in press; Marsh, 2004; Pahl & Rowsell, 2010). Teachers who work within a sociocultural framework of teaching reading attempt to build a variety of such materials into their formal literacy curriculum.

Sociocultural ideas on the development of reading and writing and how best to facilitate them have been influential in recent years. The model put forward by Freebody and Luke (1990) includes four sets of reading and writing practices:

- text encoder or encoding written and visual language, i.e., cracking the codes of texts;
- working with the purpose of texts, i.e., asking what this text does to me or what I might do with this text here and now;
- making or producing meaning with texts, i.e., constructing written and visual texts for social purposes;
- text analyst practices, i.e., constructing underlying values, beliefs, and views.

Crucially, sociocultural views of writing emphasize the importance of realizing that reading and writing practices do not take place in isolation from one another, nor in a vacuum. They are expressions of the context and situation as well as the wider cultural setting in which writers find themselves. In the 21st century, this entails recognition that literacy in homes and communities will be multimodal, often multilingual, and involving different scripts. It will be the responsibility of teachers to recognize this as they set about teaching in schools.

Conclusions

This brief résumé of the teaching of literacy (reading and writing) summarizes the contrasting theories that are held on *why* children learn to read and write as well as *how* they go about doing it and the role of the teacher in facilitating this. Cognitive views of reading and writing regard literacy as a skill which can be taught by engaging the child in mental activities (phonics learning or the learning of spelling, grammar, etc.). Within this frame-

4 TEACHING LITERACY

work, the *meaning* of a text and the purpose for which it is read or written takes second place. Sociocultural views, on the other hand, view reading and writing as inherent parts of cultural practices. Children must become familiar with each of these parts in order to be accepted as *members* of a practice. Within this frame, *cognition* is, perhaps, taken for granted under the umbrella of occurring naturally in being part of a group. Teachers have been trained with a greater or lesser emphasis on each belief, according to the political and social views of the time. This swings and roundabouts situation is unlikely to change in the near future.

Teaching Pragmatics

NAOKO TAGUCHI

Pragmatics, a subject within linguistics, focuses on how people perform, interpret, and respond to language functions in a social context. Learning a language involves more than learning grammar and lexis. The rules of proper communication, such as how to speak appropriately in a situation or understand another person's intention, are critical skills to master in order to become a fully competent speaker in another language. These objectives of pragmatics learning are represented in the connection between *pragmalinguistics* and *sociopragmatics* (Leech, 1983). *Pragmalinguistics* refers to the linguistic forms available to perform language functions, while *sociopragmatics* refers to the appropriateness of the linguistic forms in a given social context. Pragmatic competence requires both types of knowledge, as well as processing skills that mobilize this knowledge in real time communication. Learners need to have a range of linguistic forms at their disposal in order to perform language functions (e.g., greetings), but at the same time, they need to understand the sociocultural norms and rules that govern the usage of these forms (e.g., what to say to greet a certain person). Hence, in second language (L2) learning, grammar (forms), and pragmatics (rules of communication) deserve distinct attention but should be learned conjointly, because the object of pragmatics learning is form–function–context mappings—knowledge of forms and their functional possibilities, as well as contextual requirements that determine the form–function mappings.

The significance of pragmatic competence in L2 learning has been articulated in theory, pedagogy, and assessment. Theoretical models of communicative competence born in the 1980s and 1990s situated pragmatic competence as an indispensable component of L2 proficiency, apart from grammatical, discourse, and strategic competencies (Canale & Swain, 1980; Bachman & Palmer, 1996). Since then, the models have served as a guiding framework for the empirical investigation of pragmatic competence, defined as speakers' *ability to perform language functions and knowledge of socially appropriate language use*. Pragmatic competence has thus been operationalized as a measurable construct, and tasks and instruments have been developed to elicit and examine it in pedagogy and assessment. Correspondingly, these models of communicative competence have been applied to pedagogy and assessment. For instance, communicative language teaching and the notional-functional approach have included pragmatics as important objectives of instruction. Standardized assessment measures such as ACTFL (American Council of Teachers of Foreign Languages, 1999) and the Common European Framework (Council of Europe, 2001) have also designated pragmatic competence as part of the target construct of measurement. These trends have fortified the claim that pragmatic competence should be taught and assessed.

Having recognized the prominence of pragmatics in the field, this entry will review three central issues in the teaching of pragmatic competence: targets of pragmatic instruction, instructional practice and materials, and current challenges in pragmatics teaching.

Instructional Targets: What Pragmatics Can Be Taught?

The selection of focal pragmatic features for instruction clearly reflects disciplinary histories. Following the first appearance of the term “pragmatics” in Charles Morris's (1938) *Theory*

2 TEACHING PRAGMATICS

of *Signs*, a number of influential pragmatics theories were born in the field. Austin's (1962) speech act theory, Searle's (1969) taxonomy of speech acts and the distinction between direct and indirect speech acts, Brown and Levinson's (1978) politeness theories (see also Leech, 1983), Grice's (1975) cooperative principles and conversational implicature, and Sperber and Wilson's (1995) relevance theory all served as a common framework for examining pragmatic phenomena across languages and language users. The concepts and terminologies stemmed from these theories have provided a platform for organizing units of instruction in pragmatics.

By far, speech acts (e.g., requests, refusals, apologies, compliments, and compliment responses) have been the most popular goals of instruction because of their clear connections among linguistic forms, language functions, and social context. Typically, syntactic forms and strategies used to realize speech acts are taught in conjunction with situational variables that determine the degree of politeness and indirectness of the forms (i.e., power relationship, social distance between the interlocutors, and the degree of imposition). For example, Rose and Ng (2001) used film segments containing compliment exchanges to teach common syntactic formulas of compliment speech act in English:

NP {is, looks} (really) ADJ (e.g., That dress is really nice.)
I (really) {like, love} NP (e.g., I really love that dress.)
PRO is (really) (a) (ADJ) NP (e.g., That's really a nice dress.)

In conjunction with the compliments, learners were taught a range of compliment response types (i.e., acceptance, deflections, and rejection), and were also made aware that deflection is a preferred strategy.

Other instructional studies have dealt with the comprehension of implicature, namely the ability to comprehend speakers' intentions conveyed in an indirect, nonliteral manner (e.g., Bouton, 1999). In those studies, learners were exposed to dialogues that contained implicature and were explicitly taught how to interpret them. Examples include the Pope-question implicature (e.g., Saying "Is the Pope Catholic?" in response to a question whose answer is obviously affirmative) and implicature based on Grice's maxim of relevance (e.g., responding to the question "Did you like the movie?" by saying "I was glad when it was over").

Other more recent pragmatics approaches and their neighboring fields have also informed the choice of instructional goals in pragmatics. Studies have incorporated sociolinguistic notions of register variation and speech styles such as address terms, for example, formal *V*-form and informal *T*-form in German (Belz & Kinginger, 2003) and formal versus informal speech styles encoded in grammar (Ishida, 2009). Research in discourse functional linguistics and conversation analysis have led researchers to conclude that interactional devices such as discourse markers, pragmatic routines, patterns of small talk, and deixis are important pragmatic features to teach. For example, the learning target in Liddicoat and Clozet's study was an appropriate response to the French question, *T'as passé un bon week-end?* ('Did you have a good weekend?'). Students learned the logistics of how to respond to this question and project attentive listener behavior.

A target area that has received far less attention is fluency when performing these pragmatic functions. Pragmatic fluency, like other areas of fluency, has recently received empirical attention as an aspect of pragmatic competence that characterizes speedy and efficient processing of pragmatic knowledge. Research has shown that accuracy and fluency are distinct components of pragmatic performance: they do not develop in parallel and are affected differently by contextual and individual factors (e.g., Taguchi, 2008, in press). There are only two instructional studies that are targeted at improving pragmatic fluency. House (1996) examined speech rate, pause length, and repairs in learners' production of

conversation routines, discourse strategies, and speech acts (e.g., greeting and leave-taking) in L2 English. Li (in press), on the other hand, investigated whether or not different amounts of practice could yield differential effects in the development of accurate and speedy recognition and production of request-making forms in L2 Chinese. Because empirical findings are limited, future research in the role of instruction on fluency development is promising.

Instructional Practice and Materials: How Can Pragmatics Be Taught?

Given the complexities of pragmatics that involves the connections among forms, functions, and contexts, one would naturally wonder whether pragmatic competence is indeed teachable. A bulk of studies in the 1990s showed that most aspects of pragmatics are susceptible to instruction, meaning that instruction is better than no instruction for pragmatic development. Having established the benefit of instruction, the field has evolved around a question of efficacy: What instructional methods are most effective? This question has been taken up by a line of instructional intervention studies that implemented a planned pedagogical action directed toward the acquisition of select pragmatic features. These studies compared the effect of one teaching method over another by measuring the degree of learning from pre- to post-instruction. One popular distinction used to categorize and compare instructional methods is explicit versus implicit teaching. The former typically involves explicit explanation of target pragmatic features followed by focused practice, while the latter withholds explanation but provides ample input and practice opportunities in which learners develop implicit understandings of the target pragmatic forms and their uses.

Alcón's (2007) study is an example of an intervention study that compared explicit and implicit treatment on Spanish learners of English in their acquisition of request forms in English. The explicit group received metapragmatic information regarding request-making forms. Then they were asked to find examples of requests in provided scripts and to justify their choices. The implicit group received awareness-raising tasks which featured input enhancement (i.e., requests and related sociopragmatic factors placed in bold type or capitalization) but received no metapragmatic explanation. In the posttest, both groups outperformed the control group, while no significant group differences were found in pragmatic awareness; however, only the explicit group maintained learning up to the delayed posttest given three weeks after the treatment.

Previous studies have generally confirmed the superiority of explicit over implicit instruction in teaching pragmatics, particularly when the length of instruction is short (see Jeon & Kaya, 2006, for review). However, there is evidence that teaching methods also interact with pragmatic targets. Rose and Ng (2001) found that an inductive approach was more effective for teaching pragmatic forms of complimenting, whereas a deductive approach was more advantageous for teaching the sociopragmatic rules of compliment responses (how to respond to a compliment).

Although these intervention studies have long centered around the "methods debates"—implicit versus explicit, deductive versus inductive, and production versus comprehension based instruction—the by-product of this bulk of research is a variety of teaching materials generated to teach pragmatics in the classroom. Because pragmatics entails linguistic resources for performing communicative acts in social contexts, teaching materials inevitably reflect several key elements: social context, functional language use, and interaction. Activities and tasks have been designed to incorporate these components. For example, consciousness-raising tasks have learners listen to naturalistic or scripted conversations

either live or through video or audio, with attention directed to the target pragmatic features and sociolinguistic variables of the speech events, for example, setting, participant relationships, and the level of formality (e.g., Ishida, 2009). Similarly, receptive-skills tasks expose learners to pragmatic input but have them act on them by evaluating the appropriateness of the target pragmatic forms on a rating scale or by selecting appropriate forms from a list of expressions (e.g., Takimoto, 2009). Productive-skills tasks have taken a variety of formats, including role plays, structured conversations, and discourse completion test. In role plays, students assume certain roles in hypothetical scenarios and interact with peers to practice speech acts (e.g., Pearson, 2006).

More recently, technology has brought exciting new options for the format of pragmatics teaching. There are several Web sites dedicated to L2 pragmatics (see Cohen, 2008, for review). These Web sites provide interactive multimedia modules where learners can watch video clips of conversations involving speech acts, read explanations of the speech acts and cultural tips, and complete exercises. Computer-assisted language learning (CALL) has also expanded our options of pragmatics instruction. Ward, Escalante, Al Bayyari, and Solorio (2007), for example, developed a computer program in which learners of Arabic practice back channels by producing them in response to prerecorded utterances. A computer then analyzes the timing of the back channels and provides feedback. Synchronous and asynchronous computer-mediated communication (CMC) and telecollaboration are other available instructional tools within CALL. A series of studies by Belz and her colleagues demonstrated the effectiveness of CMC in teaching speech acts, address forms, and modal particles (e.g., Belz & Kinginger, 2003). CMC offers learners an authentic context for communication by having them engage in online dialogues with native speakers during telecollaboration. Target pragmatic features appear in a contextualized manner, and the input is still, which makes it easier for learners to notice the targets. Another promising new technology is a virtual environment that simulates the computer game *Second Life*. Sykes (2009) created a virtual online space simulating a Spanish study-abroad environment. Learners of Spanish were able to move their avatars throughout the environment and interact with built-in content by practicing speech acts of requests, apologies, greetings, and service encounter interactions. This type of instructional practice brings together the key elements of pragmatic teaching—context, functional language use, and interaction—with added values of authenticity and self-discovery.

Teacher-arranged materials have been the mainstream in pragmatics teaching, as reviewed thus far. Nevertheless, previous studies have provided evidence that learners can learn pragmatic features through classroom use of the target language even when pragmatics is not an intended learning target. These studies take a language socialization approach by adapting rich, qualitative analyses of classroom input and interaction to unveil opportunities and resources for pragmatics learning. A good example is Ohta's (2001) study on the acquisition of acknowledgment and alignment expressions in L2 Japanese. In this study, acknowledgment is identified as a feedback signal used to show attentiveness in conversations (e.g., *soo desu ka* meaning "oh really"), while alignment is an emphatic feedback signal (e.g., *ii desu ne*, meaning "That's great, isn't it?"). Naturalistic recordings of classroom interactions revealed learners' gradual development of frequent, appropriate use of these signals through recycled use of them in peer talk. Collaborative peer-peer interaction created a range of opportunities for students to use the targets that were not available in teacher-fronted exchanges. These findings indicate the potential of opportunities for and outcomes of incidental pragmatics learning in different classroom practices and activities.

Another emerging venue of instructional practice for pragmatics is strategy training. Learning strategies has been a topic of L2 learning since the 1970s, owing to a seminal work by Rubin (1975) that defined learning strategies as conscious or semi-conscious learning behaviors that learners deploy to enhance their L2 knowledge and abilities. Elaborate

taxonomies of strategies (i.e., cognitive, metacognitive, and affective) have been developed and applied to teach the four language skills as well as vocabulary and grammar. Applying the concept to pragmatics, Cohen (2005) recently developed taxonomies of speech act strategies that could be used in strategy-based instruction. The taxonomies have three main categories: strategies for the initial learning of speech acts (e.g., identifying the target speech acts and gathering information about them), strategies for using the speech act material that has already been learned (e.g., using a memory aid to remember the speech act expressions), and strategies for learners' metapragmatic considerations (e.g., evaluating appropriateness of their own speech acts). These taxonomies, in part, echo the earlier claim made about the importance of autonomous learning where learners act as ethnographers and collect pragmatics information (e.g., Bardovi-Harlig, 1992), however, it advances this claim in a more systematic manner. Whether strategy training proves to be a useful option for pragmatics teaching remains for future empirical investigation.

Challenges of Pragmatics Teaching

Previous sections discussed the "what" and "how" in pragmatics teaching and presented a range of options for goals and instructional practice. This entry concludes with three challenges in teaching pragmatics. These challenges come from the nature of pragmatics that involves language use affected by considerations of language users, social context, and norms of interaction. First, teachers should be concerned about which norms to teach. For a long time, the native speaker model has been the norm of pragmatics pedagogy. In most classrooms, pragmatic behaviors by native speakers, typically inferred from native speaker intuition or through data collected from a group of native-speaking participants, are presented as optimal models for learners to emulate. However, with the rapid spread of globalization and transculturalism, the assumption of uniform native-speakerness has been increasingly challenged (Davies, 2003). In reality, there is a variety of native speakers in a given language and culture. They come from different regional, educational, and professional backgrounds, which inevitably influence the manner in which they project politeness, the criteria they use to judge appropriateness of language behaviors, and the range of linguistic repertoires they possess to perform interpersonal functions (Mori, 2009). Because it is virtually impossible to teach all varieties, one challenge of pragmatics teaching is to choose a target model that serves the purpose of instruction, but at the same time to afford students opportunities to be aware of a range of pragmatic options.

Related to the selection of a target pragmatic norm, another challenge of pragmatics teaching is in the area of needs analysis. It is important to assess who the students are in class and what their individual needs are for their own language study. These analyses of needs will inform our choice of pragmatic variety to focus on in class, but at the same time, they will help us consider individuals' subjectivity when making pragmatic choices in interaction. Some learners may want to conform to the pragmatic norms and forms of the given culture, but others may elect not to use the forms, perhaps signaling a desire to maintain their identity. Empirical evidence supporting this comes from Ishihara and Tarone (2009), who reported cases in which learners of Japanese resisted pragmatic use of higher-level honorifics or gendered language based on their subjectivity, beliefs, and experiences. Pragmatics deals with situation-appropriate sociolinguistic behavior, and learners should be informed of the consequences that accompany their choice of behavior. Yet, the choice should be left to the learners themselves, and their own learning needs and goals.

The last challenging area in pragmatics teaching relates to the goal of instruction. Traditionally, teachers and researchers preselected one or two pragmatic features and taught them in a structured, fixed discourse context. This approach assumes a static view of pragmatic competence in which pragmatic competence is a constellation of bits of

pragmatic resources that have a stable property and do not change across discourse contexts and participants. However, this traditional view has been challenged by the recent poststructuralist perspective that holds pragmatic acts are dynamic in nature, constructed, and negotiated through interaction among participants (Kasper, 2006; Mori, 2009). The challenge of future pragmatics teaching, then, is to reconceptualize the goal of instruction to reflect this new epistemology. Pragmatic competence, signified by one's ability to perform language functions and one's knowledge of socially appropriate language use, should be practiced and promoted in more authentic dialogic activities where learners have choices to adapt their pragmatic resources to ongoing interactions.

Teaching Reading

WILLIAM GRABE AND FREDRICKA L. STOLLER

This entry focuses on academic reading contexts and corresponding instructional approaches. Although second language reading instruction is also carried out in early bilingual child and adult literacy contexts, academic contexts are spotlighted here because of their pervasiveness in second and foreign language settings.

Teaching reading may best be envisioned in terms of what the fluent reader, either first language (L1) or second language (L2), is able to do and how curricula are designed to guide L2 students to this level of fluency. Reading is a complex ability that requires the fluent reader to draw information from the visual features on a page and to combine this information with reader background knowledge to form a coherent interpretation of text meaning. Skilled reading involves a number of critical features:

- setting appropriate goals in line with the reader's purpose;
- drawing upon L2 linguistic resources at word, syntactic, and discourse levels;
- recognizing words rapidly and accurately;
- engaging with the text to determine main ideas and their connections;
- using strategic processing to monitor comprehension, recognize difficulties, repair possible miscomprehension, and adjust goals as needed;
- reading texts for extended amounts of time to build fluent text processing;
- maintaining a level of motivation to persist with the task through goal completion.

To prepare L2 readers for the demands of academic reading, curriculum development efforts should (a) build on research identifying reading skills, (b) recognize the need for a long-term commitment to the incremental development process, (c) take into account the fact that some skills build on the prior development of other skills and resources, and (d) recognize that students must engage in real reading from very early stages.

Research on Reading with Implications for Instruction

Many research studies have demonstrated conclusively that learners need to establish letter-sound correspondences and phonological awareness as an early skill for reading development (Ehri, 2006; McCardle, Chhabra, & Kapinus, 2008). If this skill is not well established in a learner's L1, it must be addressed in early L2 reading instruction. Vocabulary knowledge is a second critical resource for reading development. Nation (2006) estimates that 8,000–9,000 word families are required for an L2 reader to read with reasonable fluency and comprehension. Schmitt (2008) estimates that this word-family requirement amounts to receptive knowledge of approximately 35,000 different words for fluent L2 reading skills, a total that is similar to multiple English L1 vocabulary studies of high school graduates (see Stahl & Nagy, 2006; Grabe, 2009). Word recognition and passage reading fluency are strong predictors of elementary school L1 reading abilities, and also a strong predictor of poor readers through secondary school (Sabatini, 2002; Klauda & Guthrie, 2008). Evidence for the connection between L2 reading fluency and reading comprehension is beginning to emerge (Gorsuch & Taguchi, 2008). Similarly, evidence for the impact of

2 TEACHING READING

extensive reading on reading comprehension development, in L1 and L2 contexts, argues for the importance of extended exposure to print for reading development (see Grabe, 2009).

Research also demonstrates the importance of grammar knowledge, reading strategies, discourse structure awareness, background knowledge, and reading motivation for L1 and L2 reading comprehension. In several studies, grammar has been a powerful correlate of reading abilities, with similar findings in a number of reading assessment studies. Research on reading strategies has demonstrated that reading strategies, especially when taught in effective combinations, strongly influence reading comprehension (Guthrie, Wigfield, & Perencevich, 2004; McCardle et al., 2008). Discourse structure awareness is now generally recognized as important for reading comprehension (Grabe, 2009). Similarly, the importance of background knowledge, even if sometimes difficult to measure, is widely seen as a critical component of reading abilities (e.g., Klauda & Guthrie, 2008). Reading motivation, as a critical component ability for reading development, is now well documented in L1 contexts and is being explored in L2 contexts (McCardle et al., 2008; see Grabe, 2009).

These research findings, and additional research reported in Han and Anderson (2008), Hudson (2007), and Koda (2005), argue for the importance of numerous component skills and language resources for the development of reading abilities. The establishment of key reading skills and cognitive resources for reading, however, does not immediately translate into effective instructional principles or goals. These findings must be framed within overall curricular approaches to reading instruction. At present, there is interesting evidence for the effectiveness of certain approaches to L1 reading instruction; similar evidence for L2 instructional approaches, while emerging more slowly, offers helpful curriculum development principles (Hedgcock & Ferris, 2009; Anderson, 2009; Grabe, 2009). While it is important to acknowledge that no set of curricular principles can be easily imported into all instructional contexts, the list below outlines one possible set of principles that provides a reasonable starting point for building an instructional framework. Of course, the importance assigned to these principles is influenced by needs analyses, institutional and teacher perspectives, students' strengths and weaknesses as well as their language proficiency levels, and constraints imposed by time, costs, and prior teacher training.

1. Integrate skill instruction with extensive practice and exposure to print.
2. Use texts that are interesting, varied, attractive, abundant, and accessible.
3. Provide some degree of student choice in reading materials and reading activities.
4. Introduce reading skills and guide student practice by first drawing on texts in course textbooks (key skills and comprehension strategies should be exemplified initially from the texts being read in class).
5. Develop lessons structured around pre, during, and postreading.
6. Build connections between texts and student background knowledge.
7. Provide opportunities for students to experience comprehension success (consistently frustrating L2 reading experiences typically leads to student disengagement).
8. Build expectations that reading occurs in class every day or in every lesson.
9. Plan instruction around a curricular framework that:
 - promotes word-recognition skills,
 - builds a large recognition vocabulary,
 - guides comprehension-skill development,
 - builds awareness of discourse structure,
 - develops the strategic reader,
 - promotes reading fluency,
 - develops extensive reading,
 - motivates students to read,
 - integrates content learning and reading.

For the purposes of this discussion of reading instruction, the focus is on the distinct elements of the ninth principle above. A careful consideration of these features, followed by the selection of the most important ones for consistent instruction, will likely lead to a reading curriculum that can help students develop academic reading abilities.

Emphases for Reading Instruction

Promote Word-Recognition Skills

Most L2 students on an academic track at secondary and tertiary education levels will have reasonable control over word-recognition skills, but checking how quickly and accurately students can read a word list provides a useful diagnostic tool, particularly if a teacher is concerned about students' reading progress. Students who have difficulties with letter-sound correspondences can benefit from consistent word-recognition training (see Birch, 2006). Vocabulary development, extensive reading, and fluency practice lead to improved word-recognition skills as do practice with flash cards, timed word-list reading, and word-matching and word-recognition exercises.

Build a Large Recognition Vocabulary

Advanced L2 reading requires an L2 recognition vocabulary level anywhere above 10,000 words (see Nation, 2006; Schmitt, 2008). At the same time, the need for students to know the 2,000 most frequent words still retains its force as a key argument for vocabulary instruction. To institute an active vocabulary development framework in an L2 reading curriculum, carefully designed instructional activities must be built around the following eight features:

- procedures for selecting target vocabulary,
- techniques for introducing new words,
- practice opportunities,
- activities to build word-learning strategies,
- a vocabulary-rich environment to support learning,
- word-collection activities,
- tools to build motivation for word learning,
- activities that recycle texts and vocabulary.

Useful resources for exploring each of these features include Baumann & Kame'enui (2004) and Stahl and Nagy (2006) for L1 ideas, and Folse (2004), Nation (2008), and Zimmerman (2009) for L2 ideas.

Guide Comprehension-Skill Development

The ability to understand a text requires a reasonable knowledge of basic grammar, the identification of main ideas in the text, an awareness of discourse structure, and strategic processing for more difficult texts. Reading comprehension instruction—that helps students find main ideas and express what a text is about—should give some attention to directed grammar teaching, particularly at beginning and lower-intermediate levels. However, more advanced reading courses should not be structured around extensive grammar review.

Main idea comprehension is not an easy skill to teach and typically teachers *assess* comprehension rather than *teach* comprehension through postreading questions (see Anderson, 2009). Postreading comprehension questions *can* offer good instructional opportunities if teachers ask students to explain why an answer is appropriate and where the text offers

4 TEACHING READING

support for the answer. Main idea comprehension can be promoted through class discussions about how to understand a text better, what the main ideas are, how information is connected across parts of the text or to other readings, and what linkages may exist between ideas in the text and student background knowledge. Class conversations may start with postreading comprehension questions, followed by requests for further elaboration and explanations involving multiple students (Grabe, 2009).

Build Awareness of Discourse Structure

Raising students' text structure awareness represents another critical feature of reading curricula. Writers' goals determine basic discourse organization, and the specific information that a writer presents has a major impact on how a text is organized. A teacher with some knowledge of text organization and discourse signaling markers can help students build their knowledge of discourse organization. Six activities for building text structure awareness are listed below, though many more could be incorporated into reading curricula.

1. Preview texts and highlight key words that signal text structure.
2. Highlight a paragraph and decide its function in the text.
3. Fill in a graphic organizer (e.g., table, chart, graph, timeline, outline) and identify text signals that support placement of information in the organizer.
4. Identify patterns of discourse organization (e.g., cause-effect, comparison-contrast, problem-solution) and generate simple graphic displays.
5. Reorganize scrambled paragraphs and sentences to reassemble a text or to create a good summary.
6. Match main ideas and supporting information across two columns.

A number of key principles guide text structure instruction. First and foremost, this type of instruction must be consistent and continual. Second, teachers should use the texts that students are already reading for other purposes so that students see the pervasiveness of discourse structure; teachers should not introduce "special" texts to demonstrate discourse structure. Finally, students should be given the opportunity to explain to the teacher and classmates how texts are structured and how discourse structure is signaled (see Grabe, 2009; Jiang & Grabe, 2009).

Develop Strategic Reading

Strategies for reading comprehension build on linguistic resources (words, phrases, and structures) and support the basic comprehension model developed by the reader. When good readers read for careful comprehension, they actively engage academic texts through multiple strategies and a heightened level of metacognitive awareness. These strategies (adapted from Pressley, 2002, pp. 294–6) are often applied in combinations that support each other to achieve comprehension. Strategic readers typically:

- plan and form goals before reading,
- form predictions before reading,
- read selectively according to goals,
- reread as appropriate,
- monitor their reading continuously,
- identify important information,
- try to fill in gaps in the text through inferences and prior knowledge,
- make guesses about unknown words to keep reading,

- use text structure information to guide understanding,
- attempt to integrate ideas from different parts of the text,
- build interpretations of the text as they read,
- build main idea summaries,
- evaluate the text and the author and form feelings about the text,
- attempt to resolve difficulties,
- reflect on information in the text.

Teaching for strategic reading involves a number of important steps. First, teachers introduce a strategy and discuss how, when, and why to use it, and then add it to a class list. Once introduced, the strategy is practiced and fine-tuned repeatedly throughout the course. Second, teachers model combinations of strategy uses while reading aloud to the class so that students can “witness” strategies being used. Over time, students are encouraged to verbalize strategies that they are using, usually through class discussions about how to understand the text. Third, teachers promote ways to monitor comprehension. Options for students include asking if the text is making sense, rethinking goals for reading, and deciding, at certain points, what the main ideas of the text are. Fourth, students are encouraged to use multiple strategies in combination and build familiarity and automatic strategic responses to the texts that they are reading. Teaching students to become strategic is central to reading comprehension instruction and deserves greater instructional attention (see Pressley, 2006).

Promote Reading Fluency

Building word and passage reading fluency requires a curricular commitment, rather than sporadic attention. Teachers must explain to students why they are working on fluency and “sell” students on fluency, rate, and recognition activities. When fluency activities are done right, students enjoy and look forward to them.

Developing word-recognition fluency can be carried out through repetition and “beat the clock” practice with flash cards and timed readings of lists of words that have already been introduced. Students also improve word-recognition fluency when rereading texts, reading along in a text as the teacher reads aloud, and engaging in extensive reading. Passage-level fluency can also be developed through extensive reading, recycling through previously read texts to accomplish new tasks, and timed-reading activities.

Repeated reading is becoming an important component of L1 reading curricula, and many alternatives exist for providing repeated reading practice (Rasinski, 2003; Rasinski, Blachowicz, & Lems, 2006). Unassisted repeated reading involves students reading aloud short passages alone (either at school or at home) until they reach a set reading rate. Assisted repeated reading can involve students in reading a passage silently along with an audiotape, reading a passage aloud with an audiotape, reading a passage with a teacher or aide, or first listening to a passage and then reading along (among other variations).

Develop Extensive Reading

Extensive reading, to be reasonably successful, requires a significant effort in motivating students (Bamford & Day, 2002; Day & Bamford, 2002; Grabe, 2009). Students need to be aware of the goals and benefits of extensive reading. They also need to be encouraged to read extensively at every reasonable opportunity, given many opportunities to read extensively, and provided choices in their reading selections (e.g., graded readers and level-appropriate reading material). Some ways to engage students in extensive reading are listed below.

6 TEACHING READING

1. Provide many attractive reading materials.
2. Allot time for in-class free reading or sustained silent reading.
3. Create opportunities for different types of reading out of class.
4. Have a good class library.
5. Read interesting material to students.
6. Find out what students like to read and why.
7. Interest students in reading topics.
8. Share what the teacher reads and why that material is interesting.
9. Have students share and recommend reading material.

Building extensive reading skills requires long-range curriculum planning if it is to have a major impact on fluency and reading comprehension development. There is no way to get around the fact that students become good readers only by reading a lot.

Promote Motivation for Reading

Teachers commonly believe that they do not have a major role to play in student motivation for reading. This view could not be further from the truth. Few students expect to become good, fluent L2 readers. Students know that reading development is effortful, and they need motivational support from teachers and the curriculum itself. Motivation can be supported in numerous ways:

1. Have students share interests.
2. Promote the development of group cohesiveness and collaborative support with more difficult tasks.
3. Increase students' expectancy of success.
4. Have good lead-ins for major texts and tasks to build initial interest.
5. Match student skills with challenge.
6. Make the curriculum relevant to students.
7. Help learners be active participants so that learning is stimulating and enjoyable.
8. Build real levels of expertise in topics of readings.
9. Give students some degree of choice within the curricular framework.

Integrate Content Learning and Reading

Designing a reading curriculum requires decisions about which goals have a high priority and how to combine high-priority goals into a coherent educational plan. While not every component skill and knowledge base introduced in this entry can receive equal attention, one approach to building a coherent and effective reading curriculum is to combine emphases on content and language learning, often labeled content-based instruction (Stoller, 2004, 2008). Evidence from L1 reading contexts has empirically demonstrated the effectiveness of such an approach (Guthrie et al., 2004).

A content-based approach offers opportunities for extended reading, motivational learning experiences, strategic responses to increasingly complex tasks, greater choices in reading materials, and growing challenges to match growing skills. The combination of content and language learning objectives provides opportunities for integrated skills use, meaningful project work, the recycling of important skills on a regular basis, the rereading of texts, and realistic tasks for interpreting, integrating, and evaluating information from multiple texts. These types of activities are similar to those that students are likely to encounter in academic settings (Stoller & Grabe, 1997; Guthrie et al., 2004; Grabe, 2009).

Concluding Comments

This entry outlines an array of instructional practices that can be integrated into an innovative and effective framework for teaching L2 reading. A short article can only begin to identify the potential instructional options and variations that could help make a difference in L2 students' reading success. Continued explorations of effective reading instruction practices, built upon persuasive instructional research studies, are to be encouraged for the benefit of the many L2 students who need to improve their reading abilities for academic purposes.

Teaching Translation and Interpreting

CLAUDIA V. ANGELELLI

Introduction

Translation and interpreting (T&I) refers to a very specific case of language and information processing. Translation (T) entails conveying a text initially written in a source language (with or without the intention of being translated) into a target language. Although the term has been used as an umbrella term to include oral texts, it is technically reserved for written ones. Interpreting (I), on the other hand, refers to the rendition of an oral or signed text originally produced in a source language into an oral or signed text in the target language.

Since its inception, the teaching of T&I has been intertwined with language teaching. Examples are the use of translation as a way to teach foreign languages as in the grammar translation method in the 1950s, and the teaching of language enhancement courses in T&I programs as a way to improve translation skills (Angelelli & Degueudre, 2002). Although the fields of second language acquisition and the two scholarly communities of translation studies and interpreting studies have not historically engaged significantly in the sharing of knowledge and theories, they have begun to communicate more in recent years. The beginnings of this conversation can be seen in more recent works on teaching and testing for translation and interpreting (Schäffner & Adab, 2000; Colina, 2002, 2003; Angelelli, 2004, 2006).

Historical Background

The first university T&I programs were developed in Europe in the early 1940s—for example, at the universities of Geneva in Switzerland in 1941, Vienna in Austria in 1943, and Mainz-Germersheim in Germany in 1946 (Schäffner & Adab, 2000). At the time, the focus was, as it is today, on developing translation competence as well as in understanding the process of translating and producing a valid product. While translation entered academia as an object of study, programs in interpreting were developed to meet a pragmatic need. The education of interpreters was prompted by the need to ensure communication between speakers who did not share a language. After World War II, the sudden demands to train more interpreters resulted in the emergence of a newer focus on interpreting all over the world. Universities in Europe (Belgium, Denmark, France, Germany, Italy, Spain, and the United Kingdom), Asia (Taiwan, Korea, and Japan), the Americas (Argentina, Canada, Chile, Mexico, Uruguay, USA, and Venezuela), Africa (Egypt and Tunisia), and Oceania (Australia and New Zealand) began to offer courses, programs, and degrees in interpreting (Angelelli, 2004).

Current programs in T&I are of diverse nature, ranging from short undergraduate certificates to doctoral studies. Their area of specialization also varies. Some programs offer a focus on either translation or interpreting, others combine both. Undergraduate degrees tend to be more general while graduate degrees have areas of specialization such as translation and software localization, or conference or court interpreting. Courses and

2 TEACHING TRANSLATION AND INTERPRETING

programs are offered in the traditional face-to-face classroom mode, completely online, or in blended approaches that combine face-to-face with online instruction. Furthermore some programs offer students real-life experiences such as courses taught in the form of internships (e.g., in T&I agencies or companies that have T&I divisions) or via service-learning components (e.g., doing translation projects or interpreting assignments for nonprofit agencies under supervision).

In addition to courses and programs in academic settings, there is a variety of short courses and workshops offered by the T&I industry and by professional associations. The goal of many of these short courses and workshops is on training rather than education. They cover a vast array of topics, from how to use a specific software application, to how to exercise one's memory. Instructors are generally practicing professionals who rely on their experiential knowledge. Even though these courses do not substitute formal education in T&I, they are popular among individuals seeking information and wanting to build on their bilingual ability. In the USA, for example, a degree in T&I is not a requirement to exercise the profession, and thus many bilingual individuals with command of two languages and some technical knowledge in a specific field seek these courses as a quick opportunity to explore a career.

T&I Competence

The goal of T&I academic programs is to develop T&I competence. Defining competence is not an easy task. This is partly due to the fact that both translation and interpreting are highly complex activities which involve many diverse areas of knowledge and skill. There is currently no one definition of translation competence and its components that is universally accepted within the academic field of T&I studies. In fact, there is debate about how to define T&I competence and exactly how their constituent elements are to be conceptualized, broken down, and interconnected.

Wilss (1996) initially described translation competence as consisting of three primary components which include: (a) source language receptive competence, coupled with (b) target language reproductive competence, operating within (c) a supercompetence which reflects the ability to transfer the message from one language to another. This description of translation competence emphasizes that it is not merely enough to transfer a message from one language to another, but rather that there is a need to be strategic about it (Valdés & Angelelli, 2003). Presas (2000) helps us further refine the idea of Wilss's supercompetence by defining what it is that makes translation competence different than bilingual competence. She emphasizes that a competent translator uses specialized linguistic and cultural knowledge to control interference in both the reception of information from the source text and the production of the target text. Thus, the competent translator does this in part through making a transfer at the level of meaning rather than at the level of words and phrases between two connected but separate code systems, that is, two languages. Many contemporary academic definitions of translation competence view translation as a specialized type of communication. They see the translator as interpreting a text that was written to perform a function in the source language and culture and delivering it into a new form in order to perform a function in the target language and culture (Király, 1995, 2000; Cao, 1996; Neubert, 2000; Colina, 2003; and see also several papers in Schäffner & Adab, 2000). This type of functional approach to translation views translation competence as a specialized type of communicative competence.

Agreement on what constitutes interpreting competence, on the other hand, seems to be limited only to the areas of linguistic and information processing skills. As it is the case with all situated practices, however, interpreting competence goes beyond the acquisition

of linguistic and information processing skills to include skills in the following areas: interpersonal, professional, setting specific (e.g., conference interpreting, court interpreting, health-care interpreting), and sociocultural factors (Angelelli, 2006). In the area of interpersonal skills, discussions center around the role interpreters play, how they manage their agency, and how the power interpreters hold varies across settings (Angelelli, 2004). In terms of professional skills, students learn about the standards of practice and code of ethics of the profession. Because interpreting is a situated practice, student interpreters learn how their performance as conference interpreters (Sawyer, 2004) varies in comparison to their performance as court (Berk-Seligson, 2000) or medical interpreters (Angelelli, 2004), and how the different settings in which they perform impose different constraints on their work.

Students and Teachers

In T&I classrooms, students fall within a continuum of circumstantial or elective bilinguals (Valdés & Angelelli, 2003; Angelelli, 2010). It is important to appreciate the degree to which T&I require students to master a language. Unlike language courses in which students use language to communicate and errors are considered a sign of language acquisition, in T&I courses students are expected to work with almost flawless language and error tolerance is extremely low. It follows that many students will present programs with the challenge of meeting proficiency enhancement needs. On the one hand, the levels of proficiency of elective bilinguals sometimes may not be adequate to enter T&I courses (Wilss, 1996; Colina, 2002; Angelelli, 2010); for example, in the USA by the time students graduate from college having learned a second/foreign language, their language proficiency level is intermediate, high, or advanced. To account for this, some T&I programs offer language enhancement courses (Angelelli & Degueldre, 2002), which in some cases are scheduled either as prerequisites or mandatory courses during the program. Enhancing the language skills of circumstantial bilinguals, on the other hand, is also a difficult task. They generally need to work on academic language and register. Courses on these topics are not readily available in languages other than English. In addition to a high level of language proficiency, students are expected to acquire a sense of problem solving, active listening, note taking, and split attention skills in order to perform the tasks of consecutive and simultaneous interpreting. Students should also develop research techniques and acquire terminology relevant to the topic at hand.

In terms of who is in charge of a T&I classroom, individuals who teach T&I come from different paths (Colina, 2003). They can be faculty members crossing over from various related fields from either social sciences or humanities, or they can be T&I professionals or language teachers. They are also themselves either elective or circumstantial bilinguals. At present there is no degree program on T&I teacher education.

Methods and Materials

Institutions that teach T&I face common problems. In Colina's terms (2003, p. 1), in the USA the most important ones are lack of consistent pedagogical and methodological criteria on how to approach the issues of translation teaching, and course design.

In T&I teaching the relationship between theory/research and practice is similar to the one that exists in language teaching. T&I research looks at T&I both as processes and products, discusses relationships between source and target texts, focuses on quality and assessment, and the constructions of ideologies as well as power relations. In practice, teachers approach the teaching of T&I from an experiential perspective, in most cases

relying on their own work as practitioners (Colina, 2003). When theory/research and practice come together, we see T&I teachers focusing on the correspondence or lack thereof between the source and target texts, on replicating the function of the original text, and on helping students develop the discourse of the setting where the translation or interpreting assignment takes place. With a few exceptions, instructors base their teaching on their experience rather than on pedagogical principles (Colina, 2003; Kelly, 2005). This means that materials or tasks are seldom organized in order of increasing difficulty or with a pedagogical goal in mind. Rather they are organized by themes. So students move from a general text to an economic, political, or scientific one and they are asked to research and develop appropriate terminology. The underlying assumption is that practice makes perfect.

T&I teachers who generally use authentic materials to teach classes and classroom activities tend to replicate real-life assignments. In interpreting classes, for example, students are asked to read about the topic of the interpreting assignment they are about to do in both the source and target language. The goal is that students become familiar with ways of speaking as if they were experts in the field, and they must also activate their own vocabulary and knowledge in that area. In translation courses, students are asked to find parallel texts (Wilss, 1996) in the target language. The goal is for students to work with the same text types (genre) across languages.

Testing and Assessment

A deep understanding of communicative T&I competence is key to design a construct that allows us to create the most theoretically sound assessment of that competence. In T&I studies, discussions on testing center around the measurement of either the T&I product or the process. In the past, due to the background of T&I instructors (Colina, 2003; Angelelli, 2006), little attention was paid to basic principles of testing such as reliability and validity. Testing was asystematic. Currently, as a result of more sophisticated research within T&I studies and more dialogue with other areas of pedagogy and measurement, discussions about validity and reliability of tests as well as development of measurement instruments and use of rubrics have begun to emerge. The need to establish levels of performance and measurement of areas beyond linguistic and information processing skills is ahead of us. Much work still needs to be done in this area, but T&I studies have finally made the turn toward empirical work.

Teaching Vocabulary

STUART WEBB AND PAUL NATION

Teaching vocabulary effectively requires preparation and planning. Teachers need to ensure that their students are spending time learning the words that are most useful to them. Teachers also need to have clear goals for vocabulary learning during the course and make their students aware of these goals. It is also important for teachers to use an approach that will help their learners develop comprehensive knowledge of the target words, and to measure vocabulary learning in the course. The following sections will provide a brief discussion of these issues.

Which Words Should Be Learned?

The unknown words which have the greatest value to the students deserve attention in the classroom. Typically these words are the highest frequency words that remain to be learned or words which fill a special need for the learners. The most frequent words reoccur most often in spoken and written text, so they have the greatest value for comprehension and use. For example, Nation (2006) found that the most frequent 2,000 word families in the British National Corpus (BNC) accounted for just over 89% of words in the Wellington Corpus of Spoken English, and the most frequent 3,000 word families and knowledge of the proper nouns accounted for just over 96% of the words. This finding demonstrates the relative value of learning the high-frequency vocabulary. While low-frequency words still have value, they are not encountered often enough to warrant attention in the classroom. Instead teachers need to help students learn strategies to deal with low-frequency words. Using vocabulary learning strategies effectively will increase the potential for vocabulary learning outside of the classroom.

In the initial stages of vocabulary development, the most frequent 1,000 word families should be learned, followed by the most frequent 1001–2000 word families. There are several lists derived from the frequency and range of occurrence of words that are useful resources for teachers. Michael West's (1953) General Service List (GSL) and Nation's (2004) BNC word lists are perhaps the most useful. The GSL is derived from written discourse while the BNC lists are derived from both written and spoken discourse. These lists are freely available from Paul Nation's home page <http://www.victoria.ac.nz/lals/staff/paul-nation.aspx> as well as from Tom Cobb's useful vocabulary resource the Compleat Lexical Tutor <http://www.lextutor.ca/>.

Words which fill a specific need should be learned once the high-frequency vocabulary is known. Coxhead's (2000) Academic Word List is one example of useful vocabulary for students who know the highest frequency words and are planning to study at university. The list of 570 word families accounts for 8.5–10% of the words in a range of academic texts from different disciplines. Technical words are useful for those who need to learn about a specific topic and are encountered often within a particular content area. Chung and Nation (2003) found that 30% of the words in an anatomy text could be classified as technical items.

Teachers need to measure their students' vocabulary size to determine which words deserve attention in a course. Ideally, this should be done at the beginning of the course.

2 TEACHING VOCABULARY

There are several established tests which can be used, such as the Vocabulary Levels Test (Nation, 1983, 1990; Schmitt, Schmitt, & Clapham, 2001), the Eurocentres Vocabulary Size Test (Meara & Jones, 1990), the Productive Levels Test (Laufer & Nation, 1999), and the Vocabulary Size Test (Nation & Beglar, 2007). The Vocabulary Levels Test is most useful for determining the extent to which students know the highest frequency vocabulary. The Vocabulary Size Test is also very useful because it can provide some indication of vocabulary knowledge at each 1,000-word level up to the 14,000-word level, and it measures total vocabulary size.

What Are the Vocabulary Learning Goals?

Teachers should have clear vocabulary learning goals for their students. This is particularly important in the early stages of vocabulary development when increasing vocabulary size will have a significant effect on the degree to which learners can use and understand language. The goals should be dependent on the time available for vocabulary learning inside and outside of the classroom and the methods used for learning. Explicit learning methods are fast and efficient. For example, research on learning word pairs has shown that learners can acquire from nine to 58 L2 vocabulary items per hour with an average of 34 (Thorndike, 1908), to as many as 166 L2 words per hour (W.B. Webb, 1962). More recently, Cobb and Horst (2001) found that deliberate learning with concordances for an hour a week for two months resulted in 140–80 words learned (around 16 to 20 words per hour). In comparison, incidental learning gains are relatively small, and are dependent on the amount of input; words are learned gradually through repeated encounters in context. For example, in the L1 learning context, where there is typically a large amount of input each day, young native speakers may incidentally learn approximately 1,000 word families each year (Nation, 2001). However, in an EFL (English as a foreign language) context where L2 input is limited, incidental vocabulary learning may not have as much effect on increasing vocabulary size (Cobb, 2007). Researchers tend to agree that an approach that combines explicit and incidental learning conditions may be most effective (Nation, 1990, 2001; Laufer, 2003; Hunt & Beglar, 2005 and also <http://nflrc.hawaii.edu/rfl/>; Webb, 2007a).

Learners need to be aware of the vocabulary learning goals. If teachers expect a specific number of words to be learned each week, and over the duration of a course, knowledge of these goals may encourage learning. Moreover, learners should understand how these goals can help them to reach certain vocabulary size thresholds which may allow them to better understand the target language. For example, a vocabulary size of 3,000 word families and knowledge of proper nouns might be sufficient for comprehension of television programs (Webb & Rodgers, 2009a) and movies (Webb & Rodgers, 2009b); a vocabulary size of 6,000–7,000 word families may be necessary for comprehension of conversation; and a vocabulary size of 8,000–9,000 word families may be necessary to understand novels and newspapers (Nation, 2006). Making learners aware of their vocabulary size at the start of a course and the vocabulary learning goals within the course can help them to see the value of working toward both the course and the threshold goals. If there is a principled approach to vocabulary learning within the institution, it may also be possible to indicate when learners might be able to reach certain goals such as understanding conversation and television programs. These are goals for receptive learning. For productive use, smaller vocabulary sizes may be sufficient. Michael West developed minimal productive vocabularies for speaking and for defining words that consisted of much less than 2,000 words. However, judgments of the quality of writing are positively affected by a richer vocabulary and so such limited productive vocabulary sizes need to be seen as intermediate goals.

Table 1 Description of vocabulary knowledge (taken from Nation, 2001)

Form	Spoken	R What does the word sound like?
		P How is the word pronounced?
	Written	R What does the word look like?
		P How is the word written and spelled?
Meaning	Word parts	R What parts are recognizable in this word?
		P What word parts are needed to express the meaning?
	Form and meaning	R What meaning does this word form signal?
		P What word form can be used to express this meaning?
	Concept and referents	R What is included in the concept?
		P What items can the concept refer to?
	Association	R What other words does this make us think of?
		P What other words could we use instead of this one?
Use	Grammatical functions	R In what patterns does this word occur?
		P In what patterns must we use this word?
	Collocation	R What words or types of words occur with this one?
		P What words or types of words must we use with this one?
	Constraints on use	R When, where, and how often would we expect to meet this word?
		P Where, when, and how often can we use this word?

Note. R = receptive knowledge, P = productive knowledge

How Will Vocabulary Be Learned in the Course?

Once the vocabulary learning goals for a course have been decided, teachers need to plan how those words will be learned. An awareness of the different aspects of vocabulary knowledge may help teachers to create a plan that leads to comprehensive vocabulary development. Although tests typically equate vocabulary knowledge with successfully linking form and meaning, knowing a word involves much more. Developing fluency with a word involves knowing its form, meaning, and use, and being able to use and understand the word in a native-like manner. Table 1 provides a useful description of vocabulary knowledge.

Table 1 shows that to effectively learn words there needs to be some focus on developing both receptive and productive knowledge, and there also needs to be emphasis on learning the form, meaning, and use of each word. This means that if we expect our learners to fully learn a word, completing a single activity will probably not be sufficient. Table 1 shows what is involved in gaining depth of knowledge of a word. This knowledge is gradually acquired and is typically not the result of one piece of teaching or learning. That is why Nation (2001) introduced “the four strands” as a framework for planning an effective vocabulary learning program. The notion of the four strands is that vocabulary development will be optimal if there is a similar amount of time given to learning in each strand. The four strands are meaning-focused input, meaning-focused output, language-focused learning, and fluency development.

4 TEACHING VOCABULARY

Meaning-focused input involves learning through listening and reading, with the primary goal being comprehension and enjoyment. In the meaning-focused input strand the lexical demands should be minimal and approximately 98% of the words that are encountered should be known to learners. This is supported by research that indicates that when learners know 98% of the words in written text, they are able to read and understand text without assistance (Hu & Nation, 2000). Reading and listening to material that is at this level of difficulty may allow learners to focus their attention on the unknown words. Nation (2001) suggests that knowing 98% of the words in a text provides the ideal conditions to successfully guess words in context. In meaning-focused input, learners make gradual gains in vocabulary knowledge through repeated encounters with unknown words in context. Words that teachers believe that their students know may also be enriched through encounters in original contexts. Extensive reading and listening are most commonly associated with meaning-focused input.

In the meaning-focused output strand, the aim is for learners to strengthen and deepen their vocabulary knowledge by using recently encountered words in speech and writing. One of the challenges of this strand for teachers is to design tasks that require the use of the target vocabulary in original contexts. One way this can be achieved is by placing the target words within the instructions and making it necessary for the students to use those words to successfully complete the task (Nation & Newton, 2009). Through meaning-focused output learners can increase all aspects of their productive knowledge of words.

The strand which is typically associated with vocabulary learning is language-focused learning. In this strand the aim is to explicitly focus students on learning words and to train learners how to effectively use vocabulary learning strategies. The highest frequency words deserve deliberate teaching in the classroom. Teachers may wish to spend a reasonable amount of time teaching several aspects of knowledge for important words or they may spend less time and focus on a single aspect of knowledge (typically form and meaning). Word cards, vocabulary notebooks, intensive reading, and activities that involve linking form and meaning are some examples of language-focused learning activities. Teaching vocabulary learning strategies is also an important part of this strand because there are too many low-frequency words in a language to teach, and teachers need to ensure that their students can effectively deal with low-frequency words outside of the classroom. The strategies which have the greatest value are guessing from context, learning from word cards, using word parts, and dictionary use (see Nation, 2001, for a detailed description of each strategy). Helping learners gain morphological awareness of inflections and regular, productive derivational affixes can result in better knowledge of word families. If students can use these strategies correctly, they should be able to learn more words because the potential for successful vocabulary learning will increase. It is important for teachers to make time to teach each strategy over a number of classes and check to make sure their students can successfully use them. There is plenty of evidence that deliberate learning quickly results in stable learning (Laufer, 2005), and this learning results in the kind of knowledge needed for normal language use. Any course that includes deliberate learning will give better results than one that does not include this important strand.

It is important that there are spaced multiple encounters with each word. While there is no fixed minimum number of repetitions, the general consensus is that there should be at least somewhere between 7 and 16 meetings with each word. There is an enormous amount of evidence that spaced learning is much more effective for long-term recall than massed learning. Repetition is very important for learning and repetition in new contexts is particularly important as it enriches as well as strengthens previous knowledge (Joe, 1995).

The aim of the fluency development strand is for known words to be used or understood in a more native-like manner. It is one thing to know the meaning of a word and another to be able to use it fluently. Activities that focus on fluency involve using very easy material with familiar content that does not contain any unknown vocabulary, grammatical features, and discourse features. There should also be some pressure to achieve a higher speed. Activities that are commonly associated with fluency development are speed reading and the 4/3/2 task, where a learner speaks to another learner on a topic for four minutes, then gives exactly the same talk to another learner for three minutes, and finally to a third learner for two minutes.

Vocabulary development will be enhanced if learning occurs in all four strands because while each strand may help facilitate vocabulary knowledge to some extent, they are not likely to be effective in developing comprehensive vocabulary knowledge. For example, if words are learned incidentally through extensive reading in meaning-focused input, learners may gain information that was provided in the contexts to some degree. However, their knowledge will be derived solely from what could be gained from those contexts. Encountering words in context can lead to gains in all aspects of knowledge (Webb, 2007b) but the extent to which learners may be able to successfully use those items may be limited.

Activities that build on the knowledge initially gained in one strand can strengthen and deepen learning. For example, if learners are first given the meanings of words in a language-focused learning task, their understanding and use of those words will be limited to what could be gained through the meanings provided. Encountering those words again in meaning-focused input may consolidate knowledge and has the potential to expand on the knowledge initially gained. The meaning of words can be elaborated upon when encountered in meaning-focused input, and learners may gain greater awareness of how those words are used. Meaning-focused output activities can help expand productive knowledge. Activities from the fluency strand move learners toward a more native-like use of vocabulary. While teachers cannot be expected to micromanage the learning of each word, they should find that if they try to incorporate a range of activities from each strand over a course, learners develop greater knowledge of target vocabulary than if target words were only encountered in one or two strands.

How Will Vocabulary Learning Be Assessed?

Measuring vocabulary knowledge during a course can have several benefits. First, it shows learners the value that is placed on vocabulary learning. Vocabulary learning does not have to play a central role in course assessment. However, a lack of assessment may indicate to learners that vocabulary learning is a peripheral goal that is of lesser importance than other language-learning goals. Short quizzes may be sufficient to demonstrate the need for a continued focus on vocabulary learning. A second reason for measuring vocabulary knowledge is that it also makes learners aware of their progress. Vocabulary tests can clearly demonstrate to learners that they have made progress in their language learning in a short period of time. This can provide encouragement for future learning. Third, tests can be created to raise awareness of the different aspects of vocabulary knowledge. For example, learners could be tested on their receptive or productive knowledge of form, meaning, derivatives and inflections, and collocations. Tests or test items could vary between the aspects of knowledge that are assessed. The use of tests measuring different aspects of knowledge may also help learners to expand on their initial learning by focusing on unknown or partially known aspects of knowledge. Finally, planned vocabulary tests can act as a cue for further encounters with target items. Teachers can plan tests at specific times to help learners consolidate their knowledge of words.

Conclusion

As we have seen, teaching vocabulary involves important decisions regarding what vocabulary learners need to focus on, how they will focus on it, and how they can take control of their own learning. The vocabulary teacher's main task is planning so that these decisions are made and implemented in the most effective way.

Teaching Writing

ROSA M. MANCHÓN

Introduction

The significance of developing the ability to express oneself in writing cannot be overestimated. As noted by a leading scholar in the field, writing “is central to our personal experience and social identities, and we are often evaluated by our control of it” (Hyland, 2002, p. 1). Partly as a consequence of globalization, school and society are also expected to promote multiliteracy development, that is, literacy in more than one language. This means, for instance, that being able to write in an additional language (L2) is crucial in the lives of many professionals worldwide, for whom communicating through writing in a second language is both part of their daily professional routine and a gateway to their professional development and advancement. Academic publishing in today’s globalized world would be an obvious example of this (e.g., Belcher & Connor, 2001; Flowerdew & Li, 2009). In the realm of education, writing in an L2 is also part and parcel of students’ lives in a variety of settings. These include, but are not restricted to, (a) academic and professional contexts in which the acquisition of (new forms of) L2 literacy is crucial—for instance, language for specific purposes or English as a second language (ESL) academic writing programs; (b) content-based instruction, such as immersion or content and language integrated learning (CLIL) programs; and (c) foreign-language (FL) instruction at both university (e.g., Byrnes, Maxim, & Norris 2010) and primary and secondary school levels (e.g., Reichelt, 2009).

The relevance of writing at personal, societal, professional, and educational levels, coupled with the myriad contexts in which L2 writing is learned and taught, may explain the exponential growth of research in the field. L2 writing specialists have explored a range of theoretical concerns related to the three central components of writing, that is, the writers themselves, the texts they produce, and the contexts in which they write and learn to write (see Leki, Cumming, & Silva, 2008 for a recent review). From a more applied angle, and given that, with minor exceptions, the development of literacy is contingent upon educational opportunities, pedagogical concerns have also attracted intense scholarly attention. Featuring prominently in the research agenda are attempts to elucidate the manner in which writing teachers can best respond to and assess their students’ writing, as well as how L2 writing teachers and L2 writing programs can best assist L2 writers in their efforts to express their voices, purposes, and intentions in an additional language for academic or professional purposes, participation in society, and personal growth. Disciplinary discussions have more recently added a welcome scrutiny of the role that writing can and should play in instructed second language acquisition (SLA) (e.g., Manchón, in press).

Acknowledging the variety of contexts in which writing is learned and taught necessarily implies a concomitant acceptance of the idiosyncrasy of these diverse educational settings with respect to the purposes of and approaches to the teaching of writing that characterize them. A general consensus in the field is that teaching writing should be viewed as a socially situated phenomenon, hence the need to search for locally relevant pedagogies. This is so because learning and teaching writing in each context is dependent

upon a unique combination of educational values, material and personal conditions, and social practices that are not, and should not be taken to be, universal and, therefore, generalizable across contexts and learners/users. It is also collectively agreed that teaching writing, in whichever guise, is not a neutral and value-free enterprise—to the contrary, many voices have been raised to acknowledge the importance of the educational, ethical, ideological, and sociopolitical dimensions of diverse and divergent understandings of literacy (and writing) and, consequently, of the pedagogical options endorsed when teaching it.

Three Broad Perspectives on Purposes for the Teaching of Writing

The teaching of writing may be guided by two main purposes, generally referred to as “learning to write” and “writing to learn,” the latter including learning both content and language. In *learning-to-write* conditions, writing is learned and taught as an end in itself, and the ultimate aim of the teaching program is to facilitate the development of (multi)literacy for educational or job-related purposes, as well as for full participation in society. Learning-to-write programs are associated with, for instance, (a) composition classes for ESL students, basic writers, Generation 1.5 members, heritage language learners, and remedial writers (Matsuda, Cox, Jordan, & Ortmeier-Hooper, 2006); (b) adult L2 literacy classes; (c) language for specific purposes (LSP) programs, especially for academic purposes (e.g., Leki, 2001a); or (d) writing support offered in writing centers (Williams & Severino, 2004). In contrast, in *writing-to-learn* conditions, writing is viewed as a means to an end. While writing to learn has so far been equated with *learning disciplinary subject matter in the content areas* (e.g., Newell, 2006), we will see in later sections in this entry that in an SLA-oriented line of inquiry, writing to learn is also associated with using *writing as a tool for language learning* (Polio & Williams, 2009).

These general purposes for the teaching of writing are not mutually exclusive and can, and often do, coexist in one and the same instructional setting. This would be the case for university foreign-language degree studies, in which learning to write and writing to learn are often viewed as inseparable dimensions of the same educational project. One very clearly articulated curricular proposal in this respect is the German program at Georgetown University (Byrnes et al., 2010), which relies on writing as an ideal site for the simultaneous learning of cultural content and language. Writing is conceived of as meaning making, and the curricular progression entails the writing of a range of texts that vary in terms of which dimension of knowledge construction is in focus and in terms of the personal or social nature of the discourses and genres that are the objects of instruction.

The multiplicity of purposes in the teaching of writing, on the one hand, coupled with the variety and idiosyncrasy of contexts in which writing is learned and taught, on the other, has resulted in an equally varied repertoire of instructional options, which, in turn, have been informed by developments and insights in the fields of linguistics, composition studies, first and second language writing, language for specific purposes (especially, English for academic purposes), and instructed SLA.

Principles and Practices for Teaching Writing in Learning-to-Write Contexts

Learning-to-write contexts have undoubtedly been the most widely investigated, and they feature most prominently in the L2 writing pedagogical literature (e.g., Kroll, 1990; Hyland, 2002). This research has evolved around two main axes. On the one hand, instructional

practices have been informed by disciplinary discussions about concerns of paramount importance in the writing classroom, among which the following have attracted special attention: (a) the response to students' writing (see e.g., Hyland & Hyland, 2006); (b) the development of voice in academic writing (e.g., Carter, Lillis, & Parkin, 2009); (c) issues in writing from sources and plagiarism (e.g., Pecorari, 2008); and (d) assessment principles and practices (e.g., Weigle, 2002).

On the other hand, various approaches for teaching of writing have been implemented over the years. As noted by Silva (1990), collectively considered, they represent "a cycle in which particular approaches achieve dominance and then fade but never really disappear" (Silva, 1990, p. 11). These teaching approaches vary with respect to the degree of articulation of the curricular proposals that derive from them, and also with respect to which of the three essential elements of writing constitutes the core of the pedagogical option, that is, texts, writers, or readers and contexts of writing (Cumming, 2001). *Product-oriented approaches* (including controlled—or guided—composition and current/traditional rhetoric) place emphasis on the texts that L2 writers need or are asked to produce in educational or professional settings or for community and workplace writing. Texts are viewed as "objects" (Hyland, 2002), and the goal of the program is to help students produce different kinds of texts. The focus of instruction is on the patterns and forms of organization characteristic of various text types. Model compositions displaying the features that students are expected to use in their own writing are presented, and students are instructed in, for instance, differences among text types, ways of organizing information in paragraphs, or correct sentence structure.

In contrast, *process-oriented pedagogies* focus on the writers themselves and result in more learner-centered classrooms. Based on a view of writing as a cognitively demanding and problem-solving task, the aim of the teaching program is to help L2 writers become good writers by empowering them with the strategies deployed by expert writers and also by helping them to engage successfully in a variety of processes characteristic of expert writers' composing behavior, such as generating ideas, planning, goal setting, monitoring, evaluating, and searching for language with which to express one's intended meaning. Accordingly, the emphasis is not so much on the final product or text, but rather on the intervening processes that lead to the finished product, that is, on what the L2 writer does and should do from conception to completion of his or her own text. This explains the crucial role played by teacher scaffolding and peer interaction in this approach to the teaching of L2 writing.

Finally, *post-process approaches* include a range of pedagogies, including genre-based teaching, critical literacy, and social constructivist approaches (see Atkinson, 2003). They vary from previous approaches in, first, their conception of both texts (now seen as discourse) and writers (with an emphasis on issues of ideology and agency), and, second—and very importantly—in having added the social dimension of writing (hence the theoretical and pedagogical interest in the contexts in which writing takes place).

The most thoroughly articulated post-process curricular proposal is genre-based teaching, which encompasses several pedagogical options (see Hyland, 2004). Genre-based instruction evolves around texts and the social nature of writing. The term "genre" refers to "complex oral or written responses by speakers or writers to the demands of a social context" (Johns, 2002a, p. 3). Accordingly, the texts L2 writers are asked to produce are seen as manifestations of the use of language to achieve specific purposes, in particular situations, and for particular readers. When these discursive and social lenses are applied, composing and writers' choices are viewed as "context-dependent, motivated by variations in social activity, in writer-reader relations, and by constraints on the progress of the interaction" (Hyland, 2003, p. 21). Genre-based curricula are needs-oriented (i.e., the genres chosen for instruction are based on student needs), explicit (some forms of genre pedagogies

include explicit and systematic explanations of genre characteristics), and goal-oriented (the aim of the teaching program is to empower students with the means to be able to use language for the production of texts that are appropriate for given social purposes and contexts). These three characteristics help explain the strong linguistic basis of genre teaching.

These various approaches to the teaching of L2 writing have collectively contributed to enriching L2 writing instruction and should be viewed as complementary rather than mutually exclusive. They all have strengths and weaknesses, and they all have something to offer to teachers helping students learn to write in an additional language. As noted by Ann Johns, a leading L2 writing specialist and experienced L2 writing teacher, her long and sustained experience in composition writing has convinced her that the most effective approaches to the teaching of writing “acknowledge the complexity of the writing process as both cognitive and social” and also “assist students in researching various literacy situations and genres” (Johns, 2002b, pp. 118–19).

Principles and Practices for Teaching Writing in Writing-to-Learn-Content Contexts

This approach to the teaching of writing (mainly associated with L1 writing) focuses on the link between writing and learning disciplinary knowledge in a variety of educational settings, mainly in university contexts. The best known instantiation is the Writing Across the Curriculum (WAC) movement, two sub-approaches of which are Writing to Learn (which has been informed by various theoretical models, as recently reviewed by Newell, 2006) and Writing in the Disciplines (see Hirvela, *in press*).

The basic tenet is that writing represents an ideal site for learning content in that writing shapes thinking and can lead to a process of discovery and knowledge construction. Therefore, writing is thought to promote higher-level thinking skills (particularly critical thinking) and disciplinary learning. Accordingly, students are instructed in how to use writing in their discipline knowledge throughout the course of their studies. In his review of empirical work in the field, Hirvela (*in press*) contends, first, that L2 writers find it difficult to use writing for the mastery of disciplinary knowledge and, second, that their success is crucially related to the instructional support and guidance provided by both writing and content area teachers.

In the field of L2 writing, writing-to-learn approaches are associated with content-based instructional options. One of them is content and language integrated learning (CLIL, also known as content-based instruction or CBI in the United States). CLIL is an instructional approach that is becoming very popular in the European context at the levels of research and teaching (see Ruiz de Zarobe & Jiménez-Catalán, 2009, for a review). While to date little attention has been paid to writing in studies on European bilingual education, in general, and in CLIL in particular, some work has been done, mainly at the secondary school level. For instance, focusing on proficiency in a bilingual Spanish-Basque context, where the foreign language (English) is not used outside the classroom, two years in CLIL groups gave students a significant advantage in English writing as compared to students in a traditional EFL (English as a foreign language) class (Lasagabaster, 2008); in the same study, students in a CLIL context who were one year younger also outperformed the control group. Focusing on the texts written in two secondary CLIL history classes, a longitudinal study showed the development of features of academic register as well as the role of oral preparation as scaffolding for writing (Llinares & Whittaker, 2009). However, this research is still in its infancy with respect to writing and we are, therefore, a long way away from being able to derive pedagogical implications for the teaching of writing in CLIL contexts. The same applies to other forms of content-based instruction, in which the

empirical research base available has not translated into systematic guidelines for the teaching of writing, partly due to the low priority that the development of writing skills has been given in the empirical research agenda.

Principles and Practices for Teaching Writing in Writing-to-Learn-Language Contexts

This dimension of writing instruction is linked to disciplinary discussions about the role and teaching of writing in instructed SLA. These have evolved around three main issues: (a) the language-learning potential associated with literacy practices (e.g., Manchón & Roca, 2007); (b) the various ideological, educational, and material consequences (for both teachers and students and at both personal and institutional levels) that may derive from introducing writing into school programs (Leki, 2001b); and (c) the ethical and educational dimensions of teacher preparation programs for the teaching of writing in distinct foreign-language contexts (Casanave, 2009).

In her review of the research on the potential of writing for supporting language learning, Manchón (in press) concluded that the available empirical evidence suggests that writing fosters L2 learners' engagement in a number of processes which are thought to be conducive to language learning, particularly practice, focus on form, noticing, and metalinguistic reflection, and that these benefits can be leveraged in both individual and collaborative writing. However, many more open questions exist regarding what type of learning results from the linguistic processing fostered by writing. Manchón (in press) concluded that, tentatively, research findings might be interpreted as suggesting that these potential learning outcomes appear to be dependent on task-related and learner-related variables, such as (a) whether or not L2 writers are given sufficient time to complete their writing tasks (so that they can engage in the type of problem-solving behavior posited to foster language learning); (b) whether or not the interaction engaged in during collaborative writing results in collaboration and mutual scaffolding (so that the full potential of collaborative dialogue and mutual scaffolding is exploited); (c) whether or not the pedagogical intervention requires students to engage in explicit, deep processing learning conditions (so that deeper levels of noticing and reflection are promoted); and (d) whether or not learning conditions entail an iterative process of written output, some form of input/feedback on one's own writing, noticing and reflection processes and, finally, rewriting and revised written output.

Conclusion

The teaching of L2 writing should be seen as encompassing a whole range of pedagogical contexts in which writing is learned and taught, in ways that are shaped in great part by the varied purposes for the learning and teaching of writing, which in turn lead writing teachers to draw on varied principles and practices for guiding their writing instruction. This explains why teaching writing must necessarily be seen as a socially situated phenomenon, hence the sustained effort of researchers and practitioners over the years to search for theoretically grounded and locally relevant pedagogies.

Technology and Culture

DAVID MALINOWSKI

Introduction

Technology and culture: perhaps few words are more commonly uttered when making reference to the conditions under which language learning and teaching today take place. Whether explicitly or implicitly, *technology* regularly frames discourse and practices of language learning and teaching: as Chapelle (2009) has observed, the vertical spread of technology through language classrooms and curricula has led to a situation in which “the historically-constructed line between applied linguists who work in CALL [computer-assisted language learning] and those who produce other forms of language learning materials is difficult to maintain” (2009, p. 67). And, in light of the social turn in second language acquisition and the move in applied linguistics toward a conception of competence that is both “translingual and transcultural” (Modern Language Association, 2007), *culture* is irrefutably central to the language learning endeavor.

Yet what makes technology and culture such an interesting pairing is the fact that, while both in some sense form *contexts* for language learning and teaching (language learning is often said to happen “in culture,” and “through technology”), learning culture is often also posited as a *goal* of language learning, while learning technology is not. Since the calls in the 1990s for language learners to move beyond communicative competence and develop *intercultural* communicative competence (Byram, 1997, and also discussed below), an approach to language education that incorporates critical awareness of one’s own and target cultures has been regarded as essential. Less prominent in applied linguistics research is the assertion that learners and educators ought to cultivate a critical awareness of technology as well. Yet, as Kramsch, A’Ness, and Lam (2000) argue, technological mediation does not just enhance the same cultural learning—or “culture game”—that is taking place off-screen and offline. Rather, technology fundamentally changes the nature and rules of the game itself.

Accordingly, this entry will attempt to draw connections between technology and culture that show these concepts to be mutually implicated in each other—even more, perhaps, than they behave as independent variables. The following two sections introduce various perspectives on technology and culture in light of recent thinking in language learning and teaching contexts. The final section will show how these concepts apply to Internet-mediated intercultural foreign language education, an important and growing area of technology in language education (see Belz & Thorne, 2006). Throughout, the intent of this entry is to highlight the need for a critical understanding in applied linguistics of how both language and culture are transformed, or “technologized,” by their digital and networked mediation inside and outside of the language classroom—a fact of great consequence for learners’ abilities to understand and be understood, to act and relate to others, and to assume new identities in another language.

Technology Outside-In: From Tool to Medium

When theorists and practitioners of CALL, electronic or digital literacies, computer-mediated communication, and applied linguists more generally refer to “technology,” the term is often used interchangeably with “technological tools” (Levy & Stockwell, 2006, p. 2): computer applications like Microsoft Word, Web tools like blogs or wikis, virtual environments like Second Life, or desktop video-conferencing applications like Skype or iChat. Studies that explore the affordances, applications, and limits of these types of environments for language learning and teaching abound (see the Suggested Readings section below for a selection).

But, as Kern (2006) points out, *technology-as-tool* is just one metaphor for understanding the role of the computer and related technologies in language learning. Along with the *computer-as-tool* metaphor, computers are understood *as tutors* when they act as a counterpart for the language learner, helping her or him to cultivate linguistic or communicative competence. Further, with the proliferation of digital communications applications, handheld devices, and expanded contexts of use in the late 1990s and early 2000s, Kern and others argue that understanding the roles of the computer *as medium* has become of crucial importance, and of central concern to CALL research generally.

This formulation—*computer as medium*—raises questions about the limitations of terms such as “tool” or even “computer” as stand-ins for “technology,” when the teaching and learning of languages today clearly implicates not just material objects, but physical settings, spatially and temporally distributed processes, historical and cultural practices, and the bodies, minds, and imaginations of learners. Indeed, while applied linguistics has developed ever-increasing sophistication in how it conceives of language and linguistic processes, it has been criticized for viewing technology in overly simplified and deterministic ways.

Thus, in thinking about future directions for research on the role of technology in language education, applied linguists would do well to consider a broad range of evidence demonstrating linkages between the tools we use (and how we use them), on one hand, and the emergence of cultural norms, social identities, and ways of acting that become possible for learners and educators, on the other. For example, communications technology theorists such as Naomi Baron suggest that working, socializing, and studying with mobile and networked communications devices “always on” has profound social and cognitive consequences for “the kind of people we become” (Baron, 2008). Meanwhile, many philosophers of technology insist that humans, machines, and other elements of daily life *all* “act” together as equal participants in larger networks (see, for example, Latour, 1988 on “actor-network theory”). And, within the field of applied linguistics itself, the emerging strand of ecological approaches to language learning and teaching insists that learners’ subjectivities are sustained (and even produced) by the cultural, symbolic, and material elements around them (see Larsen-Freeman & Cameron, 2008). These interrelationships between people, tools, and environment are the focus of much current research on technology, and will be explored further in the final section below.

Culture, Interculture, and Transculture: Fit for Technology?

Positing that “technology” can be seen not just as a separate tool, but as deeply implicated in the formation of language learners and teachers themselves might also serve the interests of developing a nuanced view of “culture” in theory and practices of language learning and teaching. This is because, while there is wide agreement in the literature that cultural essentialism and self-serving us/them binarism should be things of the past, the idea that the teaching of culture can be separated from the teaching of language still appears

to have much currency. Yet, whether the operative concept of culture be the “Big C” approach of interpreting standardized, national Cultures as they have been thought to reside in great works of literature and national histories, or the “little c” approach that sees culture as the lived social practices, pragmatic conventions, and background knowledges of “native speakers,” theorists taking into account the contemporary condition of flows of media, people, and imaginations argue that cultures are multiple, fluid, and emergent in linguistic practice, among speakers “native” and “non-native” alike.

Here we focus briefly on the work of Michael Byram, Karen Risager, and Claire Kramsch, three figures in the last two decades’ literature on language and culture who have made important innovations in advancing the concepts of “intercultural” and “transcultural” competence. Byram’s (1997) work in defining and applying intercultural communicative competence (ICC) has been widely influential and has contributed to the development of educational policy guidelines in Europe. It posits three linguistic competences and five cultural *savoirs* (knowledges, attitudes, and skills) thought necessary for the intercultural learner to relativize her own linguistic and cultural experiences in light of the cultural other. Building upon this, Risager (2007) reinterprets ICC in the course of her major survey of the literature on language and culture teaching, seeking to map out a place for “‘the world citizen’ seen from the perspective of language and culture pedagogy” (p. 222). By treating separately the relationships between language-and-culture and language-and-discourse, and through her explorations of the semantic, pragmatic, poetic, and identity dimensions of language, she demonstrates the multileveled interweavings of language and culture in practice. Further, Risager’s work is noteworthy for thoroughly debunking the common paradigm in teaching and practice through which people and events are interpreted primarily as *national* entities.

One crucial tension that might be said to underlie Risager’s and other conceptions of ICC with respect to technology in general, though, is the nature of the wired and hyper-mediated realities populated by language learners online and off, and upon which much intercultural communication today is premised. Here the question is not so much whether language learners’ linguistic and cultural realities admit worlds that are both everyday and construed (Risager intimates it does in her work), but whether the semantic, contextual, and poetic functions of language acknowledge the ways they are refigured through the technologies in which they manifest. Here the work of Kramsch helps in understanding language and cultural learning as not just implicated in linguistic and social practice, but as *technologized* through and through—that is, where language learners’ basic subjectivities and abilities to act symbolically in the world are radically refigured by, and within, larger political and historical forces (Kramsch, 2009). As intimated in much of the literature on cyberculture, new media studies, and digital humanities (see, for example, Hayles, 2005; Silver & Massanari, 2006), the mediation of *both* the imagination and technological, material interfaces are held to make necessary a more postmodern concept of symbolic or semiotic competence. Such visions of competence place direct focus on to how cultural representations and semiotic forms are themselves constitutive of, and not just tools employed by, world citizens and classroom subjects, both virtual and real.

Technology and Culture in Practice: The Case of ICFLE

Considering these competences in light of the fact that the technologies employed in educational contexts are increasingly *social* in nature, we now direct attention to what has been termed “internet-mediated intercultural foreign language education” (ICFLE; see Belz & Thorne, 2006). Perhaps most recognizable among different genres of ICFLE is *tele-collaboration*, described by O’Dowd (2007) as “the activity of engaging language learners in interaction and collaborative project work with partners from other cultures through

the use of online communication tools such as e-mail, videoconferencing and discussion forums" (p. 4). Other modalities include tandem learning partnerships that can take place through asynchronous or synchronous exchanges of texts and opinions, and participation in established, non-educationally oriented Internet communities like discussion forums and multiplayer games.

Among these genres, the location of the technologically enabled language learner either inside or outside the language classroom may be seen to have deep consequences for the fostering of cultural and linguistic competencies. In general, telecollaboration-style interactions and certain formations of tandem learning are understood to take place within the confines of the school and university language classroom, where the problematics of the teacher's role in planning, facilitating, and evaluating intercultural dialogue have received considerable attention. Indeed, O'Dowd and others have emphasized the crucial role of the teacher in mediating e-mail and other-medium interactions between distally located partners, precisely because of the conflicts that can and do arise in telecollaborative projects. Meanwhile, it is understood that in transgeographic and often multilingual online forums, instant messaging environments, virtual worlds, and massively multiplayer online games (MMOGs), there is no teacher and no classroom proper. Indeed, the very *absence* of a teacher and any overt pedagogical framework might help to enable what Thorne (2008) terms an "immersive learning flow"; in this case, Thorne writes, "interpersonal dynamics within digitally mediated non-institutional environments enable personally relevant engagement, which in turn can be associated with a range of potential developmental trajectories" (p. 316).

A key question awaiting resolution regarding language learners' engagement with culture and (via) technology is whether and how this immersive and "personally relevant engagement"—one that is undoubtedly culturally significant—can facilitate the learner's self-awareness and critical reflection on the "differences in meaning, mentality and worldview" that characterize transcultural dialogue (Modern Language Association, 2007, p. 5). No doubt this is in part a question of precisely *how* technological tools are put to use either inside or outside of the classroom; here Thorne's (2003) concept of "cultures of use," that is, the "historically sedimented characteristics that accrue to a [computer-mediated communication] tool from its everyday use" (p. 40), would seem to be an important guidepost for both in-class teachers and out-of-class designers of ICFLE activities. However, if we are to acknowledge, as a diverse body of research does, that the proliferation of networked, multimedia technologies has not only helped to enable new learning and participation structures, foster language play, and encourage the adoption of alternate and multiple identities—but also to blur the very boundaries between language learning, socializing, and even traveling—then there would seem to be a need for language teachers and theorists to consider not just cultures-of-use, but also the operative technologies-of-users.

In his philosophical treatise *On the Internet*, Hubert Dreyfus (2001) concedes that there is much that the Internet has to offer for those who use it to *extend* their real-world information retrieval or social interactive activities. But, in the end, he finds that its horizontal organization and disembodied, anonymous participation structure lead to a loss of community, co-presence, vulnerability, responsibility, and, crucially for the interests of language learners and educators, the very ability to make meaning. Certainly, observations of this sort need to be investigated further empirically to test their applicability in the increasingly hybridized mediascape of today; certainly as well, processes of "normalization" (Bax, 2003) of computers and other learning tools throughout language classrooms and curricula are far from even, and far from complete. Nonetheless, there are numerous signs in the applied linguistics literature that critical future questions linking language, culture, and technology will hinge not just on how to use technological *tools* to enhance language learners' communicative, intercultural, or even transcultural competence, but on understanding

technological *processes* that can create, transform, and mask cultural difference and learner subjectivities.

Technology and Discourse Intonation

DOROTHY M. CHUN

Introduction

One of the first applied linguists to use the term “discourse intonation” was David Brazil, who proposed a theory of how intonation contributes to the communicative value of speech in British English, based on the work of Halliday (1970). In the introduction to his theory, Brazil stated that he was “unashamedly concerned with function” and described intonation as “a set of speaker-options formulated without explicit reference to grammar” (Brazil, 1975, pp. 1–2). What this means is that when a speaker chooses to use a particular intonation pattern, the pattern chosen is not based on common intonational patterns for statements, questions, and other grammatical structures, but is rather dependent upon the surrounding discourse in the conversation, in particular what came before (in terms of common knowledge, topic, assumptions) and in expectations and intentions for the future. Although most work to date involves English, this appears to be true for other languages as well; that is, that there are no set intonational patterns, for example, for statements or questions, because different intonational patterns are used in different contexts and within a specific discourse (see Molholt & Hwu, 2008, for examples in Mandarin Chinese).

Brazil believed that there is a small, finite number of functionally contrastive pitch configurations in English and that each of these configurations has its own meaning. “Meaning” in this context does not refer to attitudinal notions such as “expectant” or “surprised,” or to grammatically derived concepts such as “interrogative” or “declarative.” Rather, of importance is the continuous assessment of discourse by the speaker and a choice of one intonation pattern over another for the purpose of achieving coherence and cohesion in the discourse—in other words, the interactional significance of intonation. Brazil’s theory thus differed from previous theories of intonation not in proposing a different set of components, but rather in ascribing different meanings and functions (ones that derive from usage in discourse) to more or less traditional components. For work by other linguists in this subfield, see Brown, Currie, and Kenworthy (1980); Coulthard and Brazil (1981); Johns-Lewis (1986); and Ford and Thompson (1996), to name but a few.

A common belief in discourse intonation studies is that both theoretical and pedagogical models should be based on naturally and authentically occurring speech, interactions, and conversations. As Couper-Kuhlen and Selting (1996) suggested, intonation must be viewed and interpreted within the context in which it occurs, that is, is spoken. It has a signaling function within the discourse and is part of a real-time, ongoing process of interaction, where speakers react to the way in which their interlocutor is using intonation (pitch, rhythm, timing) and “conform” to it or “break away” from it. Speakers and hearers cooperate to avoid conflict and to resolve conflict when necessary. The focus is on the “reconstruction of patterns as cognitively and interactionally relevant categories which real-life interactants can be shown to orient to” (Couper-Kuhlen & Selting, 1996, p. 46).

An example of an intonational choice in context was provided by Bradford (1996): Although a falling intonational contour might be expected at the end of a statement, a speaker might choose to use a high rising terminal intonational contour (or *upspeak*) as “a bonding technique which upspeakers use to promote a sense of solidarity between

themselves and their interlocutors" (p. 23). This rising tone serves a participatory function by encouraging the hearer's continued involvement in the exchange.

The pedagogical implications of discourse intonation for language teaching have been delineated by Brazil, Coulthard, and Johns (1980), who suggested the kind of teaching syllabus that could be derived from Brazil's seminal model. Other applied linguists who have also taken discourse approaches to the teaching of intonation include Clennell (1997), who focused on equipping international students to communicate effectively in native-English-speaking universities, and Pickering (2001, 2004), who investigated tone choice by international teaching assistants (ITAs) and showed that their inability to exploit tone choice and intonational paragraphs to highlight local vs. global information structure contributed to communication failures between ITAs and their students.

Since the 1980s, the rapid development of technologies for quantifying intonational features and the increasing use of computers to visually display intonation have led researchers and teachers to investigate how technology can be used for the teaching and learning of discourse intonation (Chun, 1998, 2002). For excellent reviews of work on computer technology for teaching and researching pronunciation, see O'Brien (2006) and Levis (2007). This entry discusses specifically how technology can (a) illuminate the discourse intonation features of a language, (b) provide a visual comparison of first language (L1) and second language (L2) intonational patterns, and (c) be used effectively in software for teaching discourse intonation to L2 learners.

Using Technology to Quantify Discourse Intonation

The importance of technology for teaching discourse intonation was confirmed in a state-of-the-art chapter on research and teaching pronunciation and intonation by Jenkins (2004), who stated "Of the recent findings of pronunciation research, the most influential in terms of pedagogic developments fall into two main groupings: those concerned with issues of context and those that relate to technological advances" (pp. 109–10). In English-language teaching, intonation has been considered to be a key to effectiveness in spoken language for some time, but the use of visualization technology has been a crucial recent advance in the teaching of intonation.

Levis and Pickering (2004) showed how teaching can be enhanced by connecting technology to an understanding of how intonation functions in discourse. Their study examined two discourse-level uses of intonation, namely the use of intonation paragraph markers and the distribution of tonal patterns, and they demonstrated convincingly that speech visualization technology provides a more sophisticated understanding of how pitch functions systematically in discourse. Without technology, learners simply had to rely on their auditory perceptions of pitch changes and movement. But, according to Levis and Pickering (2004), "the use of visualization technology has made intonation practice reliably available to even those without the ability to confidently identify pitch changes" (p. 517), thus removing one of the most important obstacles to the teaching of intonation.

Sentence-level practice is insufficient for teaching how intonation is used in connected speech; what is needed is software that presents longer stretches of speech, along with explanations of the systematic meanings of discourse pitch movement. Specifically, by expanding the context of computer-based practice material to the discourse level, learners can be shown and can practice pitch patterns that mirror authentic patterns in contextualized speech. They can learn, for example, how to signal contrastive information structure by making the relevant syllable prominent, or how to choose an appropriate pitch height in order to indicate a boundary marker for a paragraph.

Molholt and Hwu (2008) described how technology can illuminate features of discourse intonation in Chinese by contrasting two versions of the Mandarin Chinese utterance *Ni*

Figure 1 Different renditions of the question *You know why, don't you?* (Chun, 2002; © John Benjamins)

zai gan shen me? 'What are you doing?' with the "neutral" pronunciation, which would use the sequence of lexical tones for each of the words in the question. The visual acoustic representations of the question asked in different contexts revealed that (a) when expressing strong curiosity in a friendly way to a child, the high pitches of the word tones are even higher than in the neutral utterance, and the final syllable ends in a *rise* (as opposed to the slight *fall* that would be used in the neutral utterance); and (b) when asking an adult the same question in a demanding way, the high pitches are much higher than in (a) and the falling intonation on the final syllable is much more abrupt a fall than in the neutral utterance (Molholt & Hwu, 2008, p. 117, Figure 5.26).

Chun (2002, pp. 220–1) illustrated how intonation in English can signal the discourse expectations of the speaker. The left-hand portion of Figure 1 shows the utterance *You know why, don't you?* with rising intonation at the end of the first clause, *You know why*, and falling intonation at the end of the second clause, *don't you*, with the questioner assuming that the listener does know why and wanting to confirm this fact. The rising intonation on the first clause may indicate a sort of reminder to the listener, who may know why but may not be willing to accept the reason.

The right-hand portion of Figure 1 shows the same words, *You know why, don't you?*, but this rendition shows falling intonation at the end of the first clause and rising intonation at the end of the second. This pattern is used when the speaker thinks or expects that the listener knows why, but then has doubts and wishes to confirm this fact. These examples illustrate the contextualized nature of intonation in discourse: The utterances are marked intonationally not to signal that they are questions or statements, but rather to signal underlying assumptions and expectations about the response. Marking shared knowledge and presuppositions is a function of intonation at the discourse level. The important principle illustrated here is that there is not a one-to-one correspondence between syntactic type and intonation pattern, but that different combinations of these structures occur, depending on pragmatic intentions and meanings.

Comparing Discourse Intonation of L1 and L2

In addition to comparing the same utterance said in different contexts within a language, another approach to teaching L2 discourse intonation is to first compare the intonation

features of L1 and L2 (or of two varieties of a language, as in the case of different varieties of English). For example, Pickering and Wiltshire (2000) studied the phonetic correlates of accent and stress that distinguish Indian English from American English dialects, and found that in the discourse of university teaching assistants lexically accented syllables are often realized in Indian English with a relative drop in frequency (pitch) and without a reliable increase in amplitude (loudness), whereas lexically accented syllables in American English reliably increase in both frequency and amplitude. The quantification of the phonetic correlates involved recording classroom discourse and acoustically analyzing the speech using the Computerized Speech Lab (CSL) software from Kay Elemetrics (now KayPENTAX, www.kayelemetrics.com).

In a similar vein, Wennerstrom (1998) compared four aspects of intonation that contribute to achieving cohesion in the lectures of native speakers of English and of Mandarin Chinese speakers lecturing in English. She found that native speakers of English (a) used higher pitch to distinguish content words from function words, (b) often used utterance-medial nonfalling boundary tones, (c) made a large distinction between contrasting and given lexical items, and (d) differentiated rhetorical units through increased pitch range at major organizational junctures. In contrast, the Chinese speakers with lower levels of English proficiency who lectured in English (a) did not use as great a pitch difference to distinguish newly introduced content words and function words, (b) often used low boundary tones in mid-utterance position, (c) did not consistently use pitch to distinguish contrasting items from given items, and (d) did not receive high speaking scores when they failed to use increased pitch range to mark topic shifts. After quantifying specific features of discourse intonation in different languages or by speakers of a language with different L1s, technology can then be used to train L2 learners; this is discussed further in the next section.

Software for Teaching and Learning L2 Discourse Intonation

An excellent example of commercially available discourse-oriented intonation materials is Streaming Speech (Cauldwell, 2002), which goes beyond sentence-level practice. Based on Brazil's theory of discourse intonation, it is targeted at advanced learners of British or American English. All of the speech samples are unscripted narratives that have been meticulously and extensively "repurposed" for pedagogical use. All of the recordings of natural spontaneous speech have been analyzed in terms of both a traditional syllabus that deals with vowels and consonants, and, more importantly, a discourse syllabus that deals with the choices that speakers make in terms of pitch and stress and the strategies they use to communicate effectively in real time. The discourse syllabus introduces the notion of the speech unit, which is described as a stretch of speech with its own rhythm, tones, and other features that make it stream-like. Learners are made aware not only of different tones (e.g., falling, level, and rising) but of their relative frequency of occurrence in English as well. Learners are taught about the use of high and low key, and how to pause in ways that are acceptable and comprehensible to listeners. There are also opportunities for learners to practice dealing with common occurrences in spontaneous speech, such as restarting after mistakes, self-correcting, and repeating themselves.

Streaming Speech provides speech unit transcriptions with notations (see Figure 2). The notations indicate the speech unit number, speech unit boundaries, tones (arrows), where the tone begins (underlined), prominent syllables (capitalized), and speed (words per minute). Learners can listen to an entire recording and can also play back selected speech units at the click of a button.

In Figure 3, the graphics (arrows and underlining), audio, and animation of the pitch movement allow learners to observe the direction of the pitch change while simultaneously hearing the utterance spoken. The use of authentic speech is in stark contrast to the vast

majority of programs for pronunciation, which use stilted, unnatural-sounding recordings, usually not based on authentic speech. The program does not incorporate automatic speech recognition (ASR) and pronunciation evaluation, which many other commercial packages purportedly offer and which will be discussed further below.

Two limitations of the software are (a) that actual fundamental frequency representations are not included, which would allow learners to see, for example, the degree of fall or rise of the pitch (this, incidentally, could easily be done using an open source program such as Praat, <http://www.fon.hum.uva.nl/praat>); and (b) that learners do not receive any kind of feedback (which could be remedied perhaps by allowing learners to record their utterances to an online voice board, e.g., Audacity, audacity.sourceforge.net, so that an instructor could provide individual feedback).

To date, there is a paucity of studies on evaluating the effectiveness of using technology to teach discourse intonation, but an excellent model for such work is provided by Hardison (2005), who employed contextualized input in prosody training for L2 speakers of English

whose L1 was Chinese. The learners received training input using Anvil, a free Web-based video annotation tool that displays both videos of a speech event and visual displays of the pitch contour (imported from phonetic tools such as Praat). Each of the participants gave a series of oral presentations, which provided the source for his or her training materials. Two groups received training input that involved both selected video segments of their presentations and displays of their pitch contours; they then practiced with the CSL software. Two other groups received training input that consisted only of the visual display of their pitch contours (without the video), which they then practiced with the CSL software. Within each of the pairs of groups, one group trained with discourse-level segments from their presentations, while the other group trained with only individual sentences. Results showed that the prosody or intonation of all four groups improved after the training, but the discourse-level input produced better transfer to novel natural discourse. The findings of Hardison's study using technology-based training, namely that "meaningful contextualized input is valuable in prosody training when the measurement is at the level of extended connected speech typical of natural discourse" (2005, p. 175), provides strong support for the effectiveness of technology to teach and train discourse intonation.

As mentioned above, ASR technology has become prevalent in commercial products for language learning. But one of the biggest obstacles to developing effective software is that prosody is a very complex phenomenon involving a number of components, including intonation (loudness and pitch), stress, accent, and rhythm (duration and pauses). Holland and Fisher (2008) acknowledged that prosody fluctuates much more than basic vowel and consonant sounds, depending on the surrounding semantic and pragmatic context of an utterance. They also noted that the enormous variation in how native speakers realize intonation and rhythm is a great challenge for developing reliable algorithms for prosodic analysis, suggesting that "One way to contend with individual variation is to express prosodic measures not in absolute but in relative terms, such as the duration of one syllable compared to an adjacent one. CALL prosody prototypes have been developed on this principle to detect learners' departures from acceptable native values of given utterances" (p. 13). For example, one difficulty that becomes obvious when using ASR software is reconciling the speed of speech of the native speaker model and the L2 learner. If the learner speaks at a slower or faster rate than the native speaker model, a comparison of the waveforms and pitch contours will not be identical unless this difference can be correctly identified and adjusted by the software. But the mere difference in speed is not necessarily problematic in terms of how native-like or acceptable an utterance sounds.

Conclusion

Although the use of intonation in discourse has been studied linguistically in many languages, this knowledge has not been applied extensively to language teaching. There are several reasons for this, the first being that prosody is a complex aspect of spoken language. Second, even though software for acoustic analyses is freely available and can display visualizations of pitch contours, most language teachers do not themselves understand the concepts of discourse intonation, much less feel able to teach them to their students. Third, although commercial software for learning pronunciation contains ASR components, the feedback that is provided to learners does not explain precisely how the learner's utterance differs from the native speaker's model utterance, nor does it quantify what must be changed in order for the utterance to be comprehensible or appropriate for the discourse. For the future, linguists, language teachers, and acoustic software engineers must collaborate in order to provide meaningful, easily interpretable feedback to learners.

Technology and Teaching Language for Specific Purposes

ESTELA ENE

Technology is constantly transforming the way we live and learn. Its applications in language teaching, learning, and research diversify with the rapid advances of technology. While some language teachers and learners may be satisfied with or contextually limited to “low-tech” audio/video equipment or the CD-ROM that accompanies almost every textbook, there are many applications that offer exciting options to be explored in education. The issues of accessibility to technology that remain are offset by notable exceptions. For example, as a result of demand and affordability, cell phones and MP3 players and the related applications (including basic language-learning software, games, instant messaging (IM), podcasting, etc.) are surprisingly accessible. The cell phone has spread where other technology is scarce, because it can replace other larger, expensive devices. “The cellphone is the fastest growing technology platform in the developing world. India is the largest market for cellphones worldwide, with the majority being bought by illiterate and semi-literate users,” who gain opportunities for “out-of-school language learning . . . [that] open the doors for employment and further education” (*Mobile and Immersive Learning for Literacy in Emerging Economies*, para 2).

Current uses of technology in language teaching comprise CALL (computer-assisted language learning) applications including asynchronous computer-mediated communication (ACMC) such as e-mail; synchronous CMC—chat, text, and instant messaging; audio and video conferencing; computer games and virtual learning environments (VLEs) (for example, Second Life or Moodle); Web-based collaborative publication tools (wikis, blogs, vlogs); social networking sites (Facebook, Twitter, MySpace, LinkedIn); distance learning via the Web or ITV (interactive television), total or partial (hybrid or blended) online instruction. Technology can enhance tasks for teaching any language skill, designing teaching materials, delivering course content, assessing learning, or conducting research. A course may employ several applications; for example, in a hybrid writing course, students may read authentic materials on the Internet, e-mail peer-reviews, video conference with the instructor, co-construct texts in a wiki, and publish on the Web. There is no prescribed number of applications one should use as long as the use of technology is pedagogically grounded. Teachers can adopt a “weak CALL approach” whereby technology is a mere “tool to facilitate learning, providing authentic material on which to work;” or see it as “the environment through which the whole learning process takes place” (Fernández Toledo, 2002, p. 253).

In technologically enhanced language teaching, many practices are explicitly or implicitly consistent with second language acquisition theories that see interaction and negotiation of meaning as central to language learning (Smith, 2003). Sociocultural theories that prize the collaborative nature of learning extend to the communities of practice (CoPs) (Wenger, 1998) in virtual environments. Corpus linguists value the authenticity of extremely large samples of language that can be accessed and manipulated via computers and even the Web.

Some instructional merits of technology are well known. CMC fosters increased interaction, learner autonomy and equality, and sociolinguistic competence (Belz, 2003). Asynchronous CMC supports planning and focus on accuracy (Thorne & Payne, 2005).

Web-supported applications offer opportunities to connect globally, interact with native speakers, mine information, and share personal and professional interests—all from the convenience of one's own (handheld) computer, anytime, anywhere. The world's adherence to technology worries many people, but most recognize that it facilitates interaction and innovation in ways that prove its value in education.

Most of the literature on language learning and technology focuses on language for general and academic purposes (LGP and LAP, respectively). English is usually the object of study, but strong teaching and research communities have developed around technology in teaching general or academic German and Spanish (for example, Belz, 2003; Oskoz & Elola, 2010). With LSP (language for specific purposes) being primarily reactive to needs rather than reflective, many implementations—excepting perhaps online teaching—go undocumented.

Web-Based Applications

The creation of the World Wide Web (WWW) in the early 1990s opened avenues in education. In the last decade, the Web has delivered the promised connectivity among people and interactive access to unprecedented amounts of information. These developments have earned the Web a renewed name: Web 2.0. It offers more than e-mail, listservs, bulletin or message boards/forums, and static screens of information. The Web's new age offers increased capability for collaboration in social networking sites (SNSs), blogs, wikis, and video-sharing sites (YouTube) accessible from computers and portable devices. Currently, major browsers allow the creation of personal learning environments (PLEs)—myYahoo!, myMSN, iGoogle—in which teachers and learners can customize their profiles with mini-applications or widgets and connect to communities with similar interests.

Integrating **e-mail** in courses is a common occurrence. E-mail addresses may be tied to a major search engine like Yahoo! or Google, an institutional closed-circuit server (intranet), or a CMS/LMS (a course/learning management system such as Blackboard, WebCT, or Desire2Learn—or D2L). E-mail lists called listservs can be easily formed from an option built into any account. Forums or bulletin/message boards are Web spaces related to certain Web sites where readers can comment on a topic by posting e-mail-like messages that will appear in chronological or topical threads. CMSs/LMSs also feature threaded discussion boards. In LSP studies, e-mail interaction has been analyzed for discourse patterns in professional environments (Jensen, 2009).

Another distinct characteristic of the modern version of the Web is that users can combine applications. The result is often a multimodal environment that blends print with photography, video or audio files, or hyperlinks. Such combinations are often encountered in **e-courses** delivered online—partially (in hybrid/blended form) or totally. Interesting uses can be seen in ESP writing courses. Hsieh and Liou (2008) supplemented their Moodle-based EAP writing course with a peer online writing and editing room (POWER) and a concordancer of academic written English (CARE), both cocreated by the authors. A **Moodle** is a CMS/LMS also known as a **virtual learning environment (VLE)** which is free and open-source e-learning software (FOSS/FLOSS) whose licensed users can access the software code and manipulate the design. Xing, Wang, and Spencer (2008) and Henry (2007) used e-courses and HTML Web sites respectively to improve the writing skills of natural science and engineering students.

LSP Web sites provide access to LSP courses offered by universities, private institutes, or teachers. The minimum amount of LSP offered by Web sites consists of separate units on basic language for business interactions—the online equivalent of pocket-size phrase books—sometimes linked to basic assessments in the form of blank-filling or multiple-choice exercises. Others specialize in English for engineering, medicine, finance, tourism

and hospitality, aviation, or business and are sometimes cataloged on professional LSP Web sites (for example, see ESP on the Web, Linguistic Funland!, Opp-Beckman & Westerfield (2008), Volterre-Fr).

Web design applications—such as Adobe Dreamweaver or the older Web-based Netscape Frontpage—are also used to achieve instructional goals. In EAP writing, Shin and Cimasko (2008) taught ESL freshman students in the USA to use Dreamweaver and Microsoft Word to create personal Web sites to publish their writing assignments. In EMP (English for medical purposes), Muangsamai (2003) asked learners to build Web pages on medical topics after critically analyzing other sites. Exposing students to English from authentic Web sources without requiring that they publish was motivational in Fernández Toledo's study (2002) on teaching and curriculum design for students of English for library and information science.

Wikis are Web spaces where the users can cocreate content by posting, coediting, revising and interlinking texts. The most famous wiki is Wikipedia—a perfect example of collaborative globally available text. Newer CMSs incorporate wikis. In language classes, wikis are usually used for group projects. WebQuests in which learners search for information on the Web often precede the cocreation of a research paper. The public Wiki Wiki Web allows users to experiment with creating new or existing wikis. Carr, Morrison, Cox, and Deacon (2007) used a wiki in a net-based political science course in South Africa and found that, despite the wiki's learner-centeredness, its transparency and novelty posed risks to the students, teachers, and tutors. To help learners overcome confusion, some have combined the use and analysis of wikis with communication via voice chat using Skype or Voice Direct (Oskoz & Elola, 2010).

Blogs are personal Web pages administered by a single individual. As written texts that contain hyperlinks and which invite responses from others, blogs too can support writing, reading, pragmatic, and research skills. Recently, multimedia blogging has become popular. In addition to text, or instead of it, blogs feature audio files (audioblogs), video extracts (vlogs), or camera phone pictures (moblogs). In ESP, Grosseck and Holotescu (2009), using Holotescu's blog *cirip.ro* as an LMS for a two-week sociology course, concluded that the medium had great positive effects on the participants' attitudes and relationships.

Social networking sites (Twitter, MySpace, Facebook, LinkedIn) are among the newest, fastest-growing and least-researched applications. They are multimedia microblogging sites in which users can congregate for personal or professional purposes. Major browsers offer account owners the option to create and invite others to networks/groups/forums (e.g., Yahoo! Groups). Customizable SNSs are useful options for those who do not work with a CMS/LMS. Ning.com is popular among educators; some SNSs were designed specifically for educational use (Colloquia and Elgg). McBride (2009) focuses on the potential of SNS in language courses primarily for general or academic purposes, acknowledging challenges (e.g., lack of student or teacher desire to join—perhaps because they are unfamiliar with the site, too busy, or prefer another SNS; diminished equality; perceived loss of status for the teacher) and suggesting tasks that can alleviate known issues.

LinkedIn, now about five years old, is a business-oriented social networking site available in English, French, German, Italian, Portuguese, and Spanish. Users post résumés, professional profiles, and mission statements; join professional organizations; and communicate on professional topics. Materials from LinkedIn can be used to analyze and teach the features of business documents or job searches.

Facebook houses the Language Exchange project, which brings together communities of language learners, teachers, and businesses looking for opportunities to practice, travel, or offer language services. Links to the video-sharing site YouTube abound. Some of the communities linked to the project are smaller networking sites themselves and can serve as an entry point into communities of language users looking to practice German, Italian, Spanish, Spanish for medicine and tourism, and English.

The new practice of social bookmarking, whereby users can tag sites by assigning a personalized key word or phrase saved as a URL, serves as a content management tool that facilitates collaborative research (Sykes, Oskoz, & Thorne, 2008).

Virtual worlds constitute “An important area that warrants significant attention in considering the relevance of mediated contexts . . . the realms of open social spaces (e.g., *Second Life*, *There*, and *Active Worlds*), massively multiplayer online gaming spaces (MMOGs) (e.g., *World of Warcraft*, *Everquest*, and *Eve Online*), and synthetic immersive environments (SIEs) (e.g., *Croquelandia* and *ZON*)” (Sykes et al., 2008, p. 534). Hadjistassou (2009) studied the use of virtual environments as a supplement to a Blackboard-mediated online business English course and reaffirmed these merits as well as concerns related to students’ familiarity with the medium.

Mobile Devices

The popularity of mobile devices and their perceived potential for enhancing language learning is linked to their ability to access the Web, which is a feature as important as (if not more important than) their portability. Their relevance to language teaching led to the term MALL (mobile-assisted language learning). The size of mobile devices predisposes them to “on-the-go” uses (e.g., daily single-word mini-lessons; blank-filling quizzes; short spoken or written texts; e-mail and blogs). Today, “[m]obile applications are more and more expected to be as full-featured as desktop applications” (Godwin-Jones, 2010, p. 6). Contemporary **smartphones**—Apple’s iPhone and iPod Touch, Google’s Android, Nokia’s Symbian, RIM’s BlackBerry (to mention only the most well known)—are handheld computers with multimedia, wireless and Web-surfing capabilities. They can handle pictures, audio and video recordings, music, clocks, calendars, games, documents, spreadsheets, and PDF files. Frequently, they are in the hands of business people, offering them access to instant translators (for example, Google translate), online dictionaries, and language games—even online language courses. The utilization of smartphones for LSP is likely to be more popular than we realize.

The global spread and profitability of language applications for mobile phones led to advanced developments, some in languages other than English. In China, Nokia models with language applications already installed access course sites through the company’s online learning site. Verizon offers translation applications for Spanish, French, Japanese, or German. The Swedish organization Learning-by-SMS.com is “believed to be the first company using this technology to teach” Spanish, French, Italian, and German. Berlitz and DailyLit offer five-minute language lessons via e-mail. Apple’s iTunes U features learning materials and lessons. In Chinese Pod, a free account gives access to daily podcasts from among over 500 existing lessons, also available in Spanish; multimedia language lessons are supplemented with transcripts and study tools (electronic flashcards, reading comprehension exercises, a pop-up dictionary, and self-assessments); and one can practice with a native speaker via mobile phone or Skype (see also www.mlearnopedia.com).

Digital audio and video players, fast becoming ubiquitous, download, store, and play audio or video files. Podcasts (a word resulted from the blending of *playable on demand* and *broadcasting*) and vodcasts (video podcasts) are audio or video files that can be downloaded through Web syndication and played on a number of devices, including digital players, phones, and computers. Language teachers and learners can record themselves and deliver files via a Web platform endowed with RSS feeds, or they can link course content to podcasts from other sites. Podcasts can enhance the teaching of speaking, listening, and culture skills, and can constitute the basis of discussions and writing assignments.

E-readers and tablet computers are some of the newest devices on the market. E-readers, such as Amazon’s Kindle and Barnes and Noble’s Nook, available since 2007, are handheld

devices that use software designed for the display of electronic, simple or multimedia texts (e-books) that can be downloaded wirelessly. E-readers can assist in developing reading and listening skills and include text-to-speech options that convert written to spoken text. **Tablet touch-screen computers** such as Apple's iPad can browse the Internet, download applications, stream media, and be synched to a desktop. Like other devices, their use in language teaching remains to be explored.

Conclusions

Today's LSP professionals and learners have at their disposal a vast array of technological devices and services, which raise some pedagogical uncertainties and offer many new areas of inquiry to explore. While technology is undoubtedly useful for supporting learner autonomy, flexibility, access, connectivity, and interest, some concerns persist. In his study of English for business purposes (EBP), Brett (2000) reached a conclusion which has since been confirmed: technology should be used regularly and meaningfully in teaching. Among evidence that instructional goals can be accomplished in e-learning, particularly with autonomous learners, we also know that some students can feel lost, especially when using online courses (Sampson, 2003). Sykes et al. (2008) review concerns related to individual differences and assessment. Basharina (2007) cautions that global e-learners will not be equally successful in their learning experiences and highlights the significance of cultural differences, while others worry that technology facilitates the supremacy of global English while aiding in its teaching.

The quick pace at which technology develops does not allow time for evaluating its educational effectiveness. In LSP, most uses are in the hands of communities that are not interested in research. It may be that the field will never be able to assess a technology fully before a new one is invented. A more thorough documentation and exploration of technology in LSP, especially in linguistic contexts other than English, would provide a more rounded perspective on this area. For now, the world of LSP and technology remains a promised land ripe for exploration.

Technology and Language Testing

DAN DOUGLAS

Introduction

The use of technology in language testing has been with us for many years—one could argue that allowing test takers to use pencils with erasers was a technological innovation at one time in language testing. Overhead projectors, slide and film projectors, audio recorders, videodiscs, and video players were once cutting-edge technologies that were incorporated into language assessment at one time or another. Computers were introduced into assessment as early as 1935, when IBM Corporation released a “test scoring machine” that could accurately score selected response tests 10 times faster than humans (Chapelle & Douglas, 2006), and computers and the Internet are now used to develop, distribute, administer, and score language tests, and deliver test results. Such technologies as podcasting, video podcasting (vodcasting), and voice/video over Internet protocols (VoIP) are being explored for their potential for language teaching and assessment, as are computer-based simulated environments, or virtual worlds, such as Second Life (Linden Lab, 2009). Computer-assisted language testing is no doubt here to stay, in spite of some well-considered misgivings on the part of language-testing professionals (e.g., see Spolsky, 2008). The key question for language test developers and users is not whether these technologies should be used for language testing, but rather include the following:

- How does language performance differ with different technologies?
- How does the use of technology affect the definition of the language ability construct we are attempting to measure?
- What are the effects of the use of technology in language assessment on test-taker attitudes such as anxiety and motivation?
- How does technology affect the nature of assessment tasks that can be developed?
- What are the limits of technology for scoring constructed response assessment tasks and how does automated scoring differ from human scoring?
- How can technology be used in test development?

The remainder of this entry will review where we are at the present time in the task of investigating these questions. Although the title of this entry is “Technology and Language Testing,” the main focus will be on computer and Internet technologies and their uses for test development, administration, delivery, scoring, and analysis.

Language Performance and Different Media

There is little question that language use is a different experience when done on a computer screen as opposed to live or print media. Mangen (2008) argues that

the particular sense of being, deeply and for an extended period of time, phenomenologically immersed that we typically experience when reading a novel, is related to and at least partly dependent on the very materiality of the print pages of the book itself. (p. 416)

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal1182

Whereas, with electronic text, by virtue of its being intangible, is at least potentially devoid of this phenomenological immersion. The same may not be true of writing: there is evidence that the composing process may be enhanced by the use of a computer over pen and paper (Barrera, Rule, & Diemart, 2001). It seems obvious that there will be differences in speaking performance when speaking with a live interlocutor versus speaking to a computer screen, even in synchronous modality, and there is research investigating the nature of the differences (e.g., Vandergriff, 2006). Having a human audience, even when the audience is silent, probably produces differences in discourse compared to speaking impersonally. Similarly, listening to live speech may result in a different comprehension process than listening to electronic speech, even when accompanied by video (e.g., Wagner, 2007). In principle, any change in the input or response technology in a language test can potentially affect the ways we process language, whether we are assessing reading, listening, writing, or speaking, or a combination of these. A question we need to ask in each case, therefore, is how these differences affect test performance, and more importantly, our interpretations of test performance.

Technology and the Construct to be Measured

In light of the point made in the previous section, we need to define the construct we wish to measure in a language test taking into account the technology being used to deliver the test and collect responses. In their book on the use of computers in language assessment, Chapelle and Douglas (2006) defined language ability in recognition of the joint role that language and technology play in communication: “the ability to select and deploy appropriate language through the technologies that are appropriate for a situation” (p. 107).

If a particular technology is a relevant aspect of a language-use situation, then a language user who is not competent in using that technology cannot be considered competent in communication in that context. In one situation, sending an e-mail message may be the appropriate way to communicate, while in another, a telephone call might be more suitable, and in yet another situation only a face-to-face conversation will do. In our language tests, therefore, we need to consider what technologies—and these include paper and pencil as well as computers and the Internet—are most appropriate for the situations most relevant to the test takers and score users, and for the purposes the test is intended to fulfill. We must define the language construct to include appropriate technology in light of the target situation and test purpose.

Technology and Test-Taker Attitudes

We know that, generally speaking, younger people are more technologically adept than those of “a certain age,” but this tendency is far from universal and many test takers find computer-assisted language tests confusing and unwieldy, not to mention communicatively unnatural. Although there is not much research on the effect of test anxiety on test performance, the findings suggest that it is moderately negative, particularly in low to intermediate proficiency learners (In’nami, 2006), although in a well-conceived study using structural equation modeling, In’nami found no effect of test anxiety among high proficiency learners on a low stakes listening test performance. In spite of such findings, we still don’t know much about the effects of anxiety in individual test takers, nor do we know very much about the effects on test anxiety brought about by computer (Taylor, Jamieson, Eignor, & Kirsch, 1998). Recent work by Wall and Horák (2008, cited in Alderson, 2009) suggest that computer familiarity, however, may be becoming less and less of a concern.

Attitude also affects the way test takers interact with the material available on a computer screen. Wagner (2007) found that when offered visual support in the form of a video in a listening test, participants oriented to the images only 69% of the time, and there was a wide range of individual variation, with some test takers looking at the screen as much as 90% of the time and others as little as 50%. Apparently, some test takers felt that the video distracted them from focusing on the aural input or that the images did not contain any information that was crucial to their comprehension.

Technology and Assessment Tasks

The above discussion suggests that different technologies might be appropriate for delivering test input and collecting responses and that these should reflect the language-use situations that are the focus of the assessment. Computers can provide images, both still and video, to suggest appropriate communicative settings and participants, and can simulate different instrumentalities, including telephone conversations, face-to-face interviews, control tower to pilot radio messages, and so on. For example, the computerized oral proficiency instrument (COPI), produced at the Center for Applied Linguistics (Malabonga, Kenyon, & Carpenter, 2005), employs

written files and audio directions in English, written and audio directions in the target language, a graphic file of a picture that accompanies the task (for those tasks that have pictures), and an audio prompt from a native speaker of the target language. (p. 63)

Similarly, Lopez, Alba-Juez, Aragones, and Molina (2006) report on the development of an instrument similar to the COPI but propose to include a voice recognition and verification system to allow for test-taker identification in a distance assessment format. Some of the developers of the Internet-based DIALANG diagnostic tests have provided some examples of experimental test tasks made possible by computer technology (Lancaster University, *n.d.*). These include the use of video and audio clips and interactive images in listening tasks, onscreen text reorganization tasks, and drag and drop listening, reading, and vocabulary tasks. These sample tasks are offered in the spirit of experimentation and are worth exploring to consider how they might affect the construct being measured. Another example of a use of technology in assessment tasks is the computer-assisted *Basic English Skills Test Plus* (BEST Plus), produced by the Center for Applied Linguistics (2009), in which the test tasks are delivered on a computer via a CD; the administrator reads the prompt from the screen, listens to the test taker's response, and enters a rating on the computer. Based on this input, the program determines the difficulty level of the next tasks and presents it. The test taker occasionally is requested to look at the screen for visual input, but does not operate the computer. Finally, Kenyon and Malabonga (2001), in a comparison of tape-mediated, computer-based, and face-to-face speaking assessments, found that participants rated the adaptive computer-based assessment "easier" since it provided input more at each participant's level of ability, while they rated the face-to-face oral assessment a better assessment of real-life speaking skills.

The Promise and Threats of Automated Scoring

Automated language evaluation and scoring programs are being used in a number of different tests at the present time. For example, the Versant series (Versant Arabic, English, Spanish, Aviation, and Junior English Tests) of speaking assessments (Pearson Education, Inc., 2009a) are delivered over telephone lines or locally on a computer and test takers'

responses are scored automatically by speech processing technology “trained” on a large sample of speakers of the language being assessed. The algorithm assesses sentence mastery, vocabulary, fluency, and pronunciation. Rate of speech, length and position of pauses, stress, and segmentation contribute to the measurement of pronunciation and fluency, while structure and vocabulary are assessed by comparing actual responses to those expected. The test publishers report a correlation between human raters and the automated Versant system at 0.97, virtually indistinguishable (Pearson Education, Inc., 2009b).

Another testing program that is exploring the use of automated scoring in both written and spoken production is TOEFL, though in lower stakes situations than claimed for Versant. The scoring of writing is done by a scoring “engine” called *e-rater*, which focuses on four types of features: syntactic, discourse, lexical, and topical (Chodorow & Burstein, 2004). Syntax is analyzed by “tagging” each word in an essay with an appropriate part of speech and then assembling these into phrasal and clausal units, providing information about the essay’s syntactic variety, while discourse is analyzed by having the program look for discourse markers such as *in summary*, *in conclusion*, and so on. Lexical features analyzed include the number of unique words in the essay and measures of word length, on the grounds that longer words reflect range, frequency, and morphological complexity. Finally, the topical score is based on analysis of topic-specific vocabulary used in the essay, compared with that used in criterion essays written by learners of different ability levels. As is the case with the Versant scoring system, *e-rater* scores show a fairly high degree of agreement with those produced by trained human raters: *e-rater* scores either match or are within one point (on a six-point scale) of humans’ scores 96% of the time (Chodorow & Burstein, 2004).

Concerns about Automated Scoring

Clearly, there are concerns among test developers and other language professionals about automated scoring. For example, Norris (2001) argues that “It is doubtful that the complexities of [speaking] performances and the inferences that we make about them will be captured by automated scoring” (p. 99). In a similar vein, with regard to the evaluation of writing, Weigle (2002) notes that “The notion that writing can be graded on the basis of linguistic features of the text rather than the message that the text conveys is understandably abhorrent to writing teachers” (p. 236). Indeed, researchers in the TOEFL program (Chodorow & Burstein, 2004), in their study exploring the validity of *e-rater*, concluded the following:

In practical terms, *e-rater* differs from human readers by only a very small amount in exact agreement, and it is indistinguishable from human readers in adjacent agreement. But despite these similarities, human readers and *e-rater* are not the same. When length is removed, human readers share more variance than *e-rater* shares with [human readers]. *The human readers must be sensitive to additional characteristics of writing that the machine is not* [emphasis added]. (p. 31)

Thus, although the developers of such automated scoring systems can show that there is a positive correlation between the scores produced by the system and those given by humans, the question remains of whether there are aspects of language production that humans are sensitive to that computers do not recognize. In other words, are humans and computers giving similar scores to an essay but for different reasons? In a study designed to explore this question, Lee, Gentile, and Kantor (2009), have found some evidence that there are

reasonably strong associations between several e-rater variables and multi-trait rating dimensions in some areas of essay quality, such as organization, vocabulary, and mechanics. This means that, for these variables, both e-rater and human raters are focusing on similar or related aspects of examinees' essays. (p. 21)

However, they also found some discrepancies between human rater dimensions and those of e-rater, and suggest further research to refine the automated system. The science, and art, of automated language evaluation is improving all the time, as applied linguists understand more about the nature of writing and speaking performance and as techniques of computer-assisted natural language processing become more and more sophisticated, but we are still some years, perhaps decades, away from being able to rely wholly on such systems in language assessment, and for the present time it would be unwise to make high stakes decisions about people based solely on assessments rated by computers. For a thoughtful, and entertaining, review of a book on the machine scoring of student essays (Ericsson & Haswell, 2006), see Cumming (2007), who emphasizes "the need to examine systematically the uses of computerized tools for writing assessment as they are actually implemented by instructors, students, and educational institutions" (p. 81).

Technology and Test Development

Apart from the uses of computer technology in the delivery and scoring of tests, there are a number of technological tools to assist in the development of language tests, including authoring tools for creating the computer-based tests themselves and language analysis tools for discovering and describing the target language features to be tested. Test authoring tools will not be discussed here. Language analysis tools are associated mainly with corpus linguistics, including discourse and conversation analysis. A language corpus is a large collection of text (upwards of a million words), representing the target language use situation related to the proposed test, that can be analyzed for its lexical properties by means of concordancers, which assist in analyzing word frequency, phrases, and collocations. Concordancers are often associated with specific corpora such as those available from Cobb (2009), which includes access to the Brown University Corpus and the British National Corpus, among others; the Linguistic Data Consortium (2009); the Michigan Corpus of Academic Spoken English (English Language Institute, 2009); and the Corpus of Contemporary American English (Davies, 2009). Concordancers provide not only information about how words and phrases are used in immediate linguistic contexts, but often allow the downloading of the entire transcript the items appear in, a particularly valuable feature in specific purpose language assessment.

Another aspect of test development that technology has made possible is not quite as overt as the tools available for computer applications: the access test developers now have to each other's expertise via the Internet through e-mail, synchronous communication, and voice-over-Internet applications such as Skype. Stansfield (2009) has pointed this out succinctly:

Location is now irrelevant. Two test developers can communicate with each other as quickly across continents as they can across the hall. This offers tremendous opportunities for test developers around the globe, in that they can pool their resources and work together anywhere. (p. 320)

Indeed, since language test development is best done in groups (see Davidson & Lynch, 2002), Internet-mediated communication can be a great boon to usually underfunded research and development teams.

Conclusion

Technology is an inescapable aspect of modern language testing and indeed can be great boon to test developers in providing for efficient, effective test construction, delivery, response, scoring, reporting, and analysis. The use of technology can enhance authenticity both through using the technology that is appropriate to a target communicative situation and using technological multimedia capabilities to highlight appropriate situational aspects of test tasks. Technology must be taken into account when defining the construct to be measured in our tests, and at various points developers are cautioned that the use of technology for its own sake can lead to the trivializing of language test tasks by limiting what we include in our tests to those things that can be delivered easily by computers or the Internet or that can be scored easily by machines. As noted at the beginning of the entry, the use of technology in language assessment really isn't an issue we can reasonably reject—technology is being used and will continue to be used. Our responsibility is to see that it is used in the service of language assessment and that language assessment is not distorted or trivialized by mindless uses of technology.

Technology and Language: Mixed Methods

YU-LI CHEN

Using technology for teaching and learning is a current challenge for language teachers, as evidenced by the various studies that have been conducted to understand why and how teachers have incorporated modern technology into their instruction (e.g., Groves & Zemel, 2000; Epper, 2001). This entry offers an overview of the advantages of applying a mixed methods research design to explore the ways language teachers adapt to current rapid technological advances. The portion of the study described in this entry used the quantitative technique of structural equation modeling (SEM) and the qualitative technique of interviews (see Chen, 2008a, 2008b, for details of the study).

Mixed Methods Research Design

Greene, Caracelli, and Graham (1989) listed five purposes for mixed research: triangulation, complementarity, development, initiation, and expansion. When a mixed methods study is applied, time order (concurrent vs. sequential) and paradigm emphasis (equal status vs. dominant status) are the dimensions to consider. That is, researchers should determine whether a qualitative phase is preceded by a quantitative one or vice versa and whether the quantitative or the qualitative phase has a dominant status.

This mixed methods study examining teachers' information and communication technology (ICT) use employed a concurrent triangulation strategy, as the quantitative and qualitative data collections both occurred in one phase. A triangulation strategy takes advantage of the strengths of one method as a means of compensating for the weaknesses inherent in the other method. According to Creswell (2003), a concurrent triangulation strategy can result in "well-validated and substantiated findings" (p. 217). Quantitative and qualitative paradigms were emphasized equally in this study.

Data analysis of the quantitative study results represented a deductive approach, while analysis of the qualitative results represented an inductive approach. Use of a triangulated strategy allows convergence of the research findings and strengthens the knowledge claim (Creswell, 2003). For these reasons, the combined use of both quantitative and qualitative methods was best for the present study to explain and explore why and how these English as a foreign language (EFL) teachers use ICT in their instructional practices.

Quantitative Phase

The strategy of inquiry used in the quantitative part of the study was a survey. The survey measured the extent to which EFL teachers in northern Taiwanese higher education used ICT and the factors which influenced their use. Understanding the variables that explain or relate to an outcome can make solutions to the problem clearer.

The Survey

A questionnaire was developed to measure the extent of ICT use in participants’ instructional practices and the factors influencing their use. All items were revised for comprehension and clarity through the procedures of literature review, think-alouds, expert reviews, and a pilot study. A total of 311 EFL teachers from northern Taiwanese higher education participated in the quantitative part of the study.

Respondents were asked to indicate agreement or disagreement with the statements on a four-point scale. After the data were collected from the actual survey, Cronbach’s alphas were initially calculated to examine the internal consistency reliabilities for all the variables in the study. Items were organized into seven major sections, reflecting the variables of interest: institutional support (internal consistency reliability .86), beliefs (.86), perceived capabilities (.84), attitudes (.76), constructivist thinking (.60), classroom pedagogy (.74), and actual Internet use (.92). Teacher training was measured by the total numbers of hours participants received training. A checklist of different types of training was provided to make sure that all the responding teachers had the same sets of criteria for this item.

SEM Analysis

A central concept for SEM models is covariance and the analysis of covariance structures. Even though most research on technology uses reported factors based on correlation and regression methods, there is more information in a covariance statistic than in a correlation statistic. The goal of SEM analysis is to understand the correlation patterns among a set of variables and to explain as much of their variation as possible with the model. SEM analysis can be viewed as a combination of path analysis and factor analysis. The full model consists of a system of structural equations. Correlations and covariances are analyzed to determine the extent to which the proposed model replicates the relationships of the observed variables (Kline, 1998; Maruyama,1998).

SEM was used to build a model that predicted the level of ICT use in language instruction of the northern Taiwanese EFL teachers. A model of the relationships among a set of eight variables frequently discussed in the literature on language studies was developed.

The Analysis of Moment Structures (AMOS) software version 7.0 was used for the SEM analysis. Performing the analysis involved specification, estimation of free parameters, assessment of fit, and modification of the model. The standardized causal effect size shows the percentage of explanation of the different latent factors. The AMOS output reports a model fit summary that contains several fit indices for the determination of the model fit with the empirical observed data (Table 1). In general, if the vast majority of the indices indicate a good fit, then there probably is a good fit. The Bentler Comparative Fit Index

Table 1 Model fit indices and suggested guidelines

<i>Model fit indices</i>	<i>Values (suggested guidelines)</i>
χ^2/df	Less than 3.0
CFI, GFI, IFI	Roughly 0.9 or larger
RMSEA	0.05 or below /good fit; below 0.08/fair fit
RMR	Roughly 0.05 or less (the smaller the better)

Source: Kline (1998); Klem (2000); Thompson (2000); McDonald & Ho (2002)

Notes: χ^2 = chi-square; *df* = degree of freedom; CFI = Bentler Comparative Fit Index; GFI = Jöreskog-Sörbom Goodness of Fit Index; IFI = Incremental Fit Index; RMSEA = root mean square error of approximation; RMR = root mean square residual.

Figure 1 Path model of Internet use

Notes: * $p < .10$, ** p -value $< .05$, *** p -value $< .001$. Number of participants = 297; $\chi^2/df = 372.164/217 = 1.175$; $p < .001$; GFI = 0.923; CFI = 0.929; RMR = 0.054; RMSEA = 0.049. For more details about the model, see Chen (2008a).

(CFI), the Jöreskog-Sörbom Goodness of Fit Index (GFI), or the Incremental Fit Index (IFI) are reported to describe the overall proportion of explained variance.

Cases with missing data were excluded, so the sample sizes decreased from 311 to 297 for the SEM analysis. Explaining the factors that influenced 297 Taiwanese EFL teachers in their use of ICT, Figure 1 indicates the variables that had either direct or indirect effects. From the SEM analysis, the presented model has adequate fit with χ^2 (chi-square) = 372.164, df (degrees of freedom) = 217, and $p < .001$.

As shown in Figure 1, teacher training was positively related to ICT use. The standardized direct effect of teacher training on ICT use was 0.56. That is, due to the direct effect of teacher education on ICT use, when teacher education goes up by 1 standard deviation, ICT use goes up by 0.56 standard deviation. Teacher training was also positively related to attitudes (.34, $p < .05$). Attitudes had a large effect on both beliefs (.67, $p < .05$) and perceived capability (.97, $p < .05$). Perceived capability mediated the effect of attitudes on ICT use. Attitudes mediated the effects of teacher training on both perceived capability and beliefs.

Qualitative Phase

The qualitative findings were intended to assist in explaining and interpreting the results of the quantitative data and to give additional insights into the issues, providing rich,

contextual understanding. According to Merriam (2002), the qualitative study is designed to “uncover or discover the meaning people have constructed about a particular phenomenon. The researcher wants to obtain an in-depth understanding of a phenomenon, an individual, a situation . . . they want to know how people do things” (p. 19). As the study was intended to discover and understand the meaning that ICT use has for the participants, data were gathered to build concepts and theories instead of testing them as in a positivist study.

The Interview Protocol

An interview protocol was developed based on the research questions, the questionnaire, and initial responses in a pilot study. Ten open-ended questions were asked (e.g., “What motivates you in using the Internet in your instructional practices?”). The purpose of the qualitative phase was to explore *what* factors influenced these teachers’ use of the Internet and to explain *how* and *why* they used the Internet. The data collected via interviews with 22 selected teachers shed light on several issues. These teachers’ replies allowed insight into different levels of ICT use and allowed the researcher to understand how these teachers applied ICT, and whether the results corroborated the findings from the quantitative study. Responses also allowed the researcher to explore other factors (than those included in the survey) that influenced teachers’ use of ICT and to determine teachers’ purposes for using ICT.

Analysis of the Interview Data

The retrieved qualitative data were analyzed from transcriptions of the interviews to identify whether there were recurring patterns or common themes among these participants. An interactive qualitative inquiry within a phenomenological framework was employed (McMillan & Schumacher, 2001; Creswell, 2003). Several themes inductively emerged. Many of the teachers interviewed used online materials to supplement classroom instruction and to expand students’ learning opportunities outside the classroom. These teachers applied ICT tools more in the listening aspects of curricular areas. Some of their ICT-based instruction, however, was primarily in the experimental phase. In addition, several teachers attempted blended teaching in their instruction.

These teachers received training in technology and they all agreed that training was crucial for their application. Since there are abundant resources and tools on the Internet, all the teachers interviewed agreed that teachers should take advantage of these. The teachers recognized that ICT integration instruction is a trend, and they complied with the school policy of using the instructional platforms their institutions provide for their long-term goals of development and with a view to creating paperless environments.

These teachers use modern technologies for different purposes. They had been trying innovation to increase students’ interest and motivation in learning. They had a commitment to continuous innovation and hoped to provide variety in instruction. In addition, they could provide updated, authentic, and multimedia instructional materials. Their ultimate goal was to assist students in developing autonomous and lifelong learning.

Major barriers and issues facing these teachers in ICT integration instruction were as follows: (a) need for time investment; (b) feelings of uncertainty when trying innovation; (c) insufficient institutional support; (d) lack of cooperation or teamwork among colleagues; (e) appropriateness of course content; (f) need for workshops focused on technology application in language instruction; and (g) lack of planning for technology integration into the classroom.

Interpretation of the Results

The results from both phases were compared and synthesized, revealing that teacher training appeared to be the most prominent determinant of ICT use. Teachers were more likely to try innovation after they received training. Teacher education affected teachers' attitudes toward ICT use, which might result in subsequent changes in classroom behavior. When teachers had positive attitudes toward ICT use, they perceived themselves as competent and were likely to use it more. Institutional support was also important, but even if institutions supported ICT use, teachers did not use it until they received more training.

These results implied that continuous professional development facilitates efficient and successful implementation of ICT use in language instruction. The results implied that teacher training is necessary for innovative methods and effective implementation of technology in instruction, as teachers should have the necessary knowledge and skills in ICT integration. However, ongoing professional programs or workshops should not be technocentric only. The results also implied that pedagogical content knowledge (Shulman, 1987) regarding technology use (Zhao, 2003) should be emphasized. Continuous professional development should be unique to language instruction and meet the needs of language teachers.

SEM Example

Because SEM is a relatively new statistical technique for applied linguistics' researchers in technology, a step-by-step example is provided below.

To start a basic SEM computation using AMOS, assume that you have an Excel or SPSS file with four (4) observed variables namely, X1, X2, Y1, Y2 (see Appendix). Again, let us

Figure 2 Procedure of SEM analysis using AMOS version 7.0: Step 1

Figure 3 Procedure of SEM analysis using AMOS version 7.0: Step 2

assume that our hypothesis states that X1 and X2 have a common implied latent variable. For example, theoretically *Incentives* (X1) and *Grants* (X2) have a common implied latent variable, *Institutional support* (F1). Then again, *Anxiety* (Y1) and *Confidence* (Y2) also have a common implied latent variable, *Attitudes* (F2). The objective of SEM is to see whether there really exists a latent variable among each of the observed variables, so as to see the strength of their relationship. At the same time, SEM can also see the strength and direction of relationship among the latent variables.

Step 1: When you open the AMOS Graphics program, you will see the basic screen as shown in Figure 2. There is a MENU at the top of the screen, while the left side shows the most commonly used short-cut ICONS. Move the cursor over the ICONS to show a brief description of their function.

Figure 4 Procedure of SEM analysis using AMOS version 7.0: Step 3

Figure 5 Procedure of SEM analysis using AMOS version 7.0: Step 4

Step 2: To start, as illustrated in Figure 3, click the DRAW LATENT VARIABLE icon three times to show the figure on the left. Do this twice, then use the ROTATE icon to rotate the figures 180 degrees. Then click and drag using the DRAW COVARIANCES icon to produce the figure on the right.

Step 3: As shown in Figure 4, click the SELECT DATA FILES icon, then click FILE NAME to select your data file. Click OK to confirm.

Step 4: Click the LIST VARIABLES IN DATA SET icon to show the listing of variables. Click and drag each of the observed variables into their respective SQUARES, as shown in the right of Figure 5.

Figure 6 Procedure of SEM analysis using AMOS version 7.0: Step 5

Figure 7 Procedure of SEM analysis using AMOS version 7.0: Step 6

Figure 8 Procedure of SEM analysis using AMOS version 7.0: Step 7

Figure 9 Procedure of SEM Analysis using AMOS version 7.0: Step 8

Step 5: Select the PLUGINS menu and click the NAME UNOBSERVED VARIABLES options as shown in Figure 6 to name all the remaining variables.

Step 6: Click the ANALYSIS PROPERTIES icon and choose the ESTIMATION tab. Select the options MAXIMUM LIKELIHOOD and ESTIMATE MEANS AND INTERCEPTS as shown in Figure 7.

Step 7: Select the OUTPUT tab, then select the options shown in Figure 8.

Step 8: Click the CALCULATE ESTIMATES icon to calculate. To show results click the VIEW TEXT icon. To see the output values, click the VIEW THE OUTPUT PATH DIAGRAM icon as shown in Figure 9.

Appendix: Sample Data for SEM Analysis

<i>X1</i> <i>(Incentives)</i>	<i>X2</i> <i>(Grants)</i>	<i>Y1</i> <i>(Anxiety)</i>	<i>Y2</i> <i>(Confidence)</i>
4	3	4	4
1	3	3	3
1	2	2	2
1	2	3	3
2	2	1	1

4	4	2	2
3	3	2	2
2	4	4	3
3	2	3	3
1	3	2	2
2	3	4	3
3	3	4	2
4	5	5	5
2	3	2	2
2	2	4	4
3	2	3	2
2	3	3	2
4	3	4	4
2	3	2	2
2	2	3	2
3	3	3	2
2	2	1	1
3	3	2	2
4	3	3	4
3	3	4	3
3	3	1	2
5	4	4	2
1	1	1	1
4	2	3	3
1	1	3	3
4	3	4	4
2	3	4	2
3	2	2	2
3	3	3	2

X1 (Incentives)	X2 (Grants)	Y1 (Anxiety)	Y2 (Confidence)
2	3	2	1
4	4	3	3
2	1	4	2
1	2	2	2
3	4	3	3
2	3	2	2
4	3	4	4
3	2	4	4
3	3	3	2
4	4	3	4
1	2	3	4
3	3	3	4
3	3	3	2
2	3	4	4
1	2	2	2
2	3	3	3
4	4	5	4
2	3	2	3

The latent variable, Institutional support (F1), is measured by two observed variables: Incentives (X1) and Grants (X2), whereas the other unmeasured variable, Attitudes (F2), is measured by Anxiety (Y1) and Confidence (Y2). The standardized causal effect size shows the percentage of explanation of the covariances or correlations between the two latent factors. From the AMOS output summary, if the vast majority of the indexes (χ^2/df , CFI, GFI, IFI, RMSEA, RMR) meet the required criteria as shown in Table 1, then there is probably a good model fit. (Note: If the resulting values do not comply with the required criteria, modify the model and run SEM again.)

Technology and Language: Overview

THOMAS COBB

The technology and language section of the encyclopedia introduces the reader to a sample of the most interesting yet representative ways that information technology (IT) is being applied to language tasks, in more than 50 specific and well-developed examples, largely but not exclusively in a language-learning context.

At first glance, language and technology are fairly distinct entities. Language technologies could be like cooking or housekeeping technologies, where the various tools and gadgets tend to make the activity easier to perform and hence less engaging both physically and cognitively. But while tools and gadgets abound for making language creating and language processing tasks easier or more efficient, as this volume attests, their overall effect is not to make us less aware of language, but more.

The language–technology link has been noticed by many, for example here by Halliday (1994, p. xxiii) with regard to sound recordings and discourse: “Perhaps the greatest single event in the history of linguistics was the invention of the tape recorder, which for the first time has captured natural conversation and made it accessible to systematic study.” But the same point can be made for other language technologies and domains of language analysis.

All language technologies, first in the guise of writing, and later in the extensions of writing, first rest on some initial analysis of what language is and does—as logographic writing rests on an awareness of words, and alphabetic writing on an awareness of sounds—and second, externalize, objectify, and stabilize language events such that we tend to become more aware of what they are and what we can do with them. This awareness-raising function of language technology is an implicit background throughout this section and is developed more explicitly in TECHNOLOGY AND LEARNING VOCABULARY.

Another implicit theme in this section is a focus on technologies that tell us something about language or let us do something with language that could not be done, or done on a significant scale, without the use of those technologies. The technologies introduced here are hence “necessary” rather than “nice.”

The awareness theme is a major focus in most of the 57 entries in this section (including biographies) that target some aspect of language acquisition, learning, instruction, or testing that directly involves language learners, normally of second languages. A further half dozen entries are more concerned with research into the nature or effects of language learning, and a similar number concern deployments of technology in investigations of language nature, use, or processing that have no immediate learner involvement. The last category includes both theoretical models of language where some form of information technology (IT) plays an integral role, as well as a selection of IT-based tools used in the linguistics professions. Four entries step outside the circle of enthusiasm to look at issues, complexities, and potential downsides to the unreflective use of language technologies, whether in the social or educational spheres.

The purpose of this overview is to group the entries in this section into provisional themes and provide links to their whereabouts, thus giving the reader a starting point for their explorations, and in that spirit links will also be provided to entries in other parts of the encyclopedia that have a significant technology component.

Technology and Language Learning

Within the Skill Areas

Contributions of technology to the first two of the “four R’s” of language learning (writing and reading, listening and speaking) are covered in entries on TECHNOLOGY AND TEACHING WRITING and TECHNOLOGY AND LITERACY, and INFORMATION RETRIEVAL FOR READING TUTORS. Listening is handled broadly in TECHNOLOGY AND LISTENING, and then both in more detail and in some mixture with speaking in TECHNOLOGY AND PHONETICS, AUTOMATIC SPEECH RECOGNITION, TECHNOLOGY AND DISCOURSE INTONATION, and two entries on text-to-speech technologies: a pedagogical entry TEXT-TO-SPEECH SYNTHESIS IN COMPUTER-ASSISTED LANGUAGE LEARNING and an entry describing the development of this technology, TEXT-TO-SPEECH SYNTHESIS DEVELOPMENT. Ways of computing the learning opportunities from both printed and spoken texts (movies) are discussed in COMPUTER-ASSISTED VOCABULARY LOAD ANALYSIS.

Across the Skill Areas

Learning technologies without a particular skill focus are probably the largest theme in this section, and these include TECHNOLOGY AND LEARNING VOCABULARY, TECHNOLOGY AND LANGUAGE TESTING, NATURAL LANGUAGE PROCESSING AND LANGUAGE LEARNING, and COMPUTER-MEDIATED COMMUNICATION AND SECOND LANGUAGE DEVELOPMENT. Four entries in this category look at the exploitation of corpora across the skills in language learning—TECHNOLOGY AND USAGE-BASED TEACHING APPLICATIONS looks in broad terms at the pedagogical uses of large standard corpora, CONCORDANCING works the same terrain more at the hands-on level, and LEARNER CORPORA and CORPUS-BASED TESTING are specific applications of the corpus idea to learning. Two entries look at multi-skill learning from an artificial intelligence (AI) perspective—a general entry, INTELLIGENT COMPUTER-ASSISTED LANGUAGE LEARNING, and a more specific entry, LEARNER MODELING IN INTELLIGENT COMPUTER-ASSISTED LANGUAGE LEARNING. Two entries look at the growing tendency for learning technologies to mean mobile technologies: MOBILE-ASSISTED LANGUAGE LEARNING (MALL) and EMERGING TECHNOLOGIES FOR LANGUAGE LEARNING. One entry describes the role of technology in creating linguistic resources such as bilingual dictionaries tailored to learning, LEXICOGRAPHY ACROSS LANGUAGES. One entry is a pedagogical adaptation of a technology originally developed a professional purpose (see below), COMPUTER-ASSISTED LANGUAGE LEARNING AND MACHINE TRANSLATION.

The work of two of the longest serving and hardest working heroes of computer-assisted language learning are celebrated in the biographies section on Frank OTTO and our general editor, Carol A. CHAPELLE.

Technology-Based Learning Environments

A special category within multi-skills is the use of technology to create a comprehensive learning communities or environments. One entry looks at these from the perspective of social networks, ONLINE COMMUNITIES OF PRACTICE, another from the perspective of multi-player immersive game environments, SECOND LANGUAGE ACQUISITION VIA SECOND LIFE. From another angle, TECHNOLOGY AND CULTURE looks at the uses of technology in recreating the cultural context of language learning. Two entries deal with the creation of learning environments in a distance-learning context, a general entry DISTANCE LANGUAGE LEARNING, and a more detailed look at the technologies involved in MULTIMODAL COMPUTER-MEDIATED COMMUNICATION AND DISTANCE LANGUAGE LEARNING.

Preparing and Measuring Success in Technology Implementation

Making good pedagogical use of such diverse and complex technological opportunities is of course far from obvious, and the section thus includes entries on both LANGUAGE TEACHER TRAINING IN TECHNOLOGY and LANGUAGE TRAINER TRAINING IN TECHNOLOGY (emphasis added). It also includes two entries on researching the effects of a technology implementation, a general entry entitled COMPUTER-ASSISTED LANGUAGE LEARNING EFFECTIVENESS RESEARCH, and another that itself employs an interesting technology to investigate not just effect but process in technology implementations (or other topics), LEARNER RESPONSE SYSTEMS IN SECOND LANGUAGE TEACHING.

The use of IT-based instrumentation in acquisition research generally is a large topic in its own right, represented here by an entry on PRIMING RESEARCH, but also as aspects of entries already mentioned such as COMPUTER-ASSISTED VOCABULARY LOAD ANALYSIS.

Beyond Pedagogy: Technology in Language Description and Analysis

At one remove from learners and classrooms are accounts of language technologies performing a broader analysis but nonetheless one intended to have implications for language learning which are perhaps not yet fully obvious. These include ANALYZING SPEECH CORPORA, LEXICAL PRIMING, LEXICAL BUNDLES AND TECHNOLOGY, and TECHNOLOGY AND PHRASES. At a different remove are the uses of technology mainly designed for native speaker language use and development, including CONCORDANCING, CORPORA AND LITERATURE, MONOLINGUAL LEXICOGRAPHY, and LEXICOGRAPHY IN NON-EUROPEAN LANGUAGES. At a further remove are analyses of what language is and how it functions at a psycholinguistic level with no obvious bearing on use or learning (yet), including CONNECTIONISM AND TECHNOLOGY and a biography entry on one of the leaders in this research, James L. MCCLELLAND.

Language Technologies and the Professions

Corpus linguistics and language instruction are of course not the only professions to deploy language technologies. TECHNOLOGY AND TRANSLATION is also an application in its own right. And behind translation technology stands the vast pinning down of lexical units and mappings in TECHNOLOGY AND TERMINOLOGY, with a glimpse into the intricacies this involves in the more detailed TERMINOLOGY AND DATA ENCODING. Language technologies are also deployed in professions not typically thought of as having a major language component, such as law, medicine, and social work; the entry EXPORTING APPLIED LINGUISTICS TECHNOLOGY looks at the application of some of the above technologies to concrete problems in medical discourse.

Managing Technology Proliferation

It has probably not escaped the reader's suspicion that many of the technologies gathered into this section have probably been developed piecemeal, without much regard to their fit within a universe of language technologies. Yet a number of subfields of technology and language have now developed to keep the whole operation moving more or less together. STANDARDIZATION IN HUMAN LANGUAGE TECHNOLOGY describes aspects of the compatibility effort in general terms, and INTERNATIONALIZATION AND LOCALIZATION deals with the more specific issue of running Web programs and pages across language boundaries.

Technology Across Section Boundaries

The present section focuses specifically on the what, how, and why of language technologies, but given the increasing integration of language and technology at any number of levels it was unlikely that this section would monopolize the topic. There are probably not many entries in this encyclopedia that do not make at least some reference to technology and language, and that is still just scratching the surface of this massive and exciting enterprise.

Preserving Perspective

Beyond the many exciting implications of the language technologies for science, culture, and education are of course the larger questions about values, winners and losers, and to what it is all leading. A biographical entry on BUSH, VANNEVAR AND HYPERTEXT, the father of hypertext, goes beyond the excitement of hypertext to assess potential downsides and unresolved issues as this mode of reading becomes dominant in our culture. An assessment of the effects of technology on education and society more broadly is discussed in LANGUAGE AND THE DIGITAL DIVIDE, and further developed in a biography entry about its author Mark WARSCHAUER. From a different angle, SEARCHLINGUISTICS argues that a major downside of a life ever more bound up with the mixed quality output of search engines is that the technology has developed faster than the linguistics—namely, searches remain largely based on words out of context, which is hardly how words are understood in either linguistics or in our minds. The unstated research question behind these reflective entries is whether any problems caused by language technologies will be solved by more technology or by less.

Reflection

This overview was intended as a useful guide to the section but may also suggest its many gaps, important topics barely mentioned, and in retrospect a lack of hierarchical signaling in the titles that might have made navigation clearer. It may also disclose the many potential overlaps between virtually all its articles that no amount of cross-referencing can fully indicate. And finally, the proposed classifications and groupings are somewhat arbitrary and might have been made differently by a different editor, or by the same one a month later! Language and technology are in a fast-moving and dynamic relationship.

Technology and Language: Quantitative Methods

LI-TANG YU, HSIEN-CHIN LIOU, AND VIPHAVEE VONGPUMIVITCH

Introduction

As time is an important variable in second language acquisition (SLA), longitudinal studies play a crucial role in research. Time-series designs (TSDs) are particularly useful in investigating effects of language instruction longitudinally (Ortega & Iberri-Shea, 2005). TSDs compensate for lack of random assignment or control groups, but require repeated observations before the treatment (to form a baseline) and after the treatment (to investigate the effects of the treatment) (Mellow, Reeder, & Forster, 1996). Inferential statistical tests are used to estimate whether changes in participants' behavior are beyond those expected by chance.

One application of TSDs is to investigate the effects of technology on language instruction. Computer technologies have the capabilities of providing a variety of input thought to be beneficial to language learners (Smith, 2004; Bush, 2008). Consequently, many researchers explore the extent to which these technologies actually facilitate language learning, particularly concerning their impact on vocabulary teaching and learning (Sun & Dong, 2004; Ma & Kelly, 2006). One tool, the concordancing program, provides learners with direct access to corpora from authentic language materials. With abundant language input, it is hypothesized that learners inductively discover the patterns and exceptions of language use. Such a language lookup process is known as "data-driven learning" (Johns, 1994), in which learners take responsibility for their learning pace, becoming autonomous learners as researchers (Bernardini, 1996). Several studies have supported the hypothesis that using concordancing helps enhance university- or tertiary-level learners' vocabulary knowledge, including vocabulary growth (Cobb, 1997), deep word processing (Horst, Cobb, & Nicolae, 2005), receptive and productive lexical competence (Lee & Liou, 2003; Chambers & O'Sullivan, 2004), and collocation knowledge (Varley, 2009).

The study described in this entry examined the effectiveness of Web-based concordancing on vocabulary learning at the primary school level, focusing on learners' development of word meaning, word usage, and sentence production using a TSD. Several vocabulary tests were administered to explore participants' vocabulary knowledge. Repeated-measures analysis of variance (ANOVA) was used to analyze the differences in vocabulary scores across time to show the participants' development of vocabulary knowledge.

Method

Participants in this study were 7 EFL fifth-graders screened out of 22 students from an intact class with varying proficiency levels but similar computer literacy. The participants had at least four years of experience learning English as a subject at school. A Chinese-English bilingual concordancing program (<http://candle.fl.nthu.edu.tw/child>) was specifically designed for Taiwanese primary school students, with a corpus taken from sentences which were modeled on those in their English textbooks (see Figure 1). To familiarize them

Figure 1 Program snapshot

with the concordancer functions and vocabulary activities, the participants were given 40 minutes of hands-on training five times.

The entire project lasted for 28 weeks. The participants' knowledge of target verbs was repeatedly examined in three phases: before the concordancing activities as the pretest phase, during the activities as the treatment phase, and after the activities as the posttest phase. The format of a vocabulary test item (see Table 1) was consistently adopted in the three phases.

Assessment in each phase involved multiple-wave data collection to closely monitor participants' progress. The procedure for data collection is shown in Table 2.

Three pretests were given to tap the participants' understanding of English verbs (those they had learned and about 60 to be learned) for the purpose of determining the baseline of their knowledge. Those verbs of which the participants missed all aspects of meanings, word usage, and sentence production were recycled again in the next pretest. The pretest was given three times in a period of 14 weeks to ensure the participants did not show word knowledge given in any of the three pretests. The findings showed each participant had 12 unknown verbs, which became their target words for learning in the treatment phase; 6 of the verbs were common to the seven participants and became our assessment target.

Table 1 Sample vocabulary test item

Feed	Chinese word meaning: (students gave the Chinese word meaning) 餵 (Chinese character of <i>to give food to</i>) Word usage: (students gave it in Chinese metalanguage as shown below) 人 + feed + 動物 + 時間 (<i>person(s) + feed(s) + animal(s) + time</i>) Sentence production: (students gave the English sentence using the target verb <i>feed</i> to correspond with the word usage above) I feed my dog every day.
------	--

Table 2 Data collection procedure

<i>Task</i>	<i>Time frame</i>
Pretest	
Pretest 1	Week 1–3
Pretest 2	Week 6–7
Pretest 3	Week 14
Treatment	
Session 1, 2, 3	Week 15
Session 4, 5	Week 16
Session 6	Week 18
Session 7, 8, 9	Week 19
Session 10, 11, 12	Week 20
Posttest	
Posttest 1	Week 21–2
Posttest 2	Week 22–3
Delayed posttest 3	Week 27–8

For the treatment, the concordancing activities were carried out in twelve 30-minute sessions over six weeks. In each session, students checked one of their unknown words of the day and looked it up in the concordancer. Then they took notes about the word's three aspects: meaning, usage, and the sentence concordance output that illustrated the word. Once the students understood the word of the day, they turned off the computer screen and completed one or two translation (Chinese) sentences adapted from the concordancing output. After completing the sentences, the students turned on the screen again and checked the answer. If time was sufficient, they reviewed the word of the day and the previous words. Lastly, when they were ready, they turned off the screen again, and finished a vocabulary test item of the day by writing down the three aspects for the target word (meaning, word usage, sentence production).

After the treatment, in order to observe the participants' growth and retention of word knowledge, they received two posttests which contained the 12 verbs studied plus 12 distracters one week after the treatment phase. Four weeks after the second posttest, they were given a delayed posttest. The two posttests and the delayed posttest contained the same items but in a different order.

A scoring method (see Figure 2) was designed by the researchers to evaluate the participants' performance on the vocabulary tests. If the participants could provide correct individual answers to the word meaning, the word usage, and the sentence production, they received one point for each aspect; otherwise, if they answered any of them wrong, they received zero for that aspect. The performance of the participants on the vocabulary tests was at first separately evaluated by both the first researcher and a graduate student majoring in teaching English to speakers of other languages (TESOL). If the scores of the word meaning, the word usage, and the sentence production given by the two raters were not uniform, the ambiguous items were marked. Final decisions were made after the two raters had discussed the ambiguities and reached 100% agreement on the scores.

Analysis

Participants' verb knowledge was operationalized as follows: (a) the average score on the three pretests, (b) the average score on sessions in the treatment, (c) the average score on

Write down the Chinese meaning,
Name: No: word usage, and a sentence of the word.
請寫出下列動詞的意義、用法與造句。

feed	意義: 飼 養	Correct! 1 point was assigned.
	用法: 人 + feed + 動物	Correct! 1 point was assigned.
	造句: I feed two dogs,	Correct! 1 point was assigned.

Figure 2 Scoring sample

the two posttests, and (d) the delayed posttest score. In order to examine the development of verb knowledge over time, the statistical procedure of repeated-measures ANOVA was selected, since all four variables to be compared were from the same participants. Because of data limitations including the sample size and normal distribution with homogeneous variance (Foster, Barkus, & Yavorsky, 2006), the nonparametric repeated-measures ANOVA (i.e., the Friedman test) was used to analyze the participants' performance.

Let us take the analysis of word usage as an example. The procedures for entering the data, running the tests, and obtaining the results in SPSS software are explained and illustrated in Figures 3–5. First, data must be entered in each column. As shown in Figure 3, you need to define which column represents what variable. Variable names are in the top of each column. The seven participants are represented by the numbers beginning each row, 1–7. Scores in the four columns represent the mean scores on the six target words the participants received on the four observation occasions.

Next, as shown in Figure 4, you need to click on the menu options ANALYZE > NONPARAMETRIC TESTS > K RELATED SAMPLES. Move the variables to the "Test Variables" box and check "Friedman." To display the descriptive statistics, click the "Statistics" button and check "Descriptive."

If a significant difference is found among the four observation occasions, a post hoc analysis is needed to ascertain where the difference lies. The Wilcoxon signed-rank test should be chosen as it allows comparison of two related variables at a time (Larson-Hall, 2010). As shown in Figure 5, click on ANALYZE > NONPARAMETRIC TESTS > 2 RELATED SAMPLES. Move the variables "pretest" and "treatment" to the right to make Pair 1 and make "pretest" and "posttest" Pair 2. The rest can be done in the same manner. It is important to note that because there are multiple comparisons (in this case, six) an adjustment must be made to the significance level to guard against Type I error. Using the Bonferroni adjustment (Larson-Hall, 2010), the significance level of .05 was divided by 6 to yield .008 as the upper level needed to claim statistical significance.

	pretest	treatment	posttest	delayedposttest	Var	Var

Results

Looking at the results of the Friedman test in Table 3 and Table 4 from the SPSS output, we can see that the mean ranks of the four variables are significantly different from one another ($\chi^2 = 16.14, p < .05$). As shown in Table 5, the results of the post hoc analysis demonstrated that the z scores calculated for the differences between the pretest on the one hand, and the posttest and the delayed posttest on the other hand, were significantly different. (Note also that the difference between the pretest and the treatment fell just short of statistical significance.) These results also show us that there were no statistically significant differences among the treatment, posttest, and delayed posttest scores.

Discussion

The participants' scores after the concordancing treatment phase significantly increased from the pretest. When the participants interacted with the target words through a concordancer, they analyzed possible word usage by testing the hypotheses via various example sentences. The benefit of such a meaningful and autonomous vocabulary learning approach seems to be supported by our research findings. In other words, these learners advanced their knowledge of the word's usage by means of concordancing consultation. These findings are in agreement with Chambers and O'Sullivan's (2004) and Lee and Liou's (2003) studies: Users can gain vocabulary knowledge through concordancing.

Table 3 Descriptive statistics of the Friedman test

<i>Occasion</i>	<i>Mean</i>	<i>Standard deviation</i>	<i>Minimum</i>	<i>Maximum</i>	<i>Mean rank</i>
Pretest	.00	.00	.00	.00	1.00
Treatment	.79	.19	.50	1.00	2.71
Posttest	.95	.07	.83	1.00	3.64
Delayed	.81	.15	.67	1.00	2.64

Note. $n = 7$.

Table 4 Results of the Friedman test

n	7
Chi-square	16.14
Degrees of freedom (df)	3
Asymptotic significance	.001*

Note. Chi-square, df , and asymptotic significance are used in the output of the Friedman test in SPSS. * $p < .05$

Table 5 Results of the Wilcoxon signed-rank test (post hoc analysis of the Friedman test)

	<i>Treatment – pretest</i>	<i>Posttest – pretest</i>	<i>Delayed – pretest</i>	<i>Posttest – treatment</i>	<i>Delayed – treatment</i>	<i>Delayed – posttest</i>
z	-2.38 ^a	-2.41 ^{a*}	-2.39 ^{a*}	-2.01 ^a	-.54 ^a	-2.02 ^b

^a Based on negative ranks. ^b Based on positive ranks. * z_{critical} for $p = .008$ is 2.39 for a directional hypothesis.

The retention of the word knowledge did decline in the delayed posttest occasion after a lapse of four weeks following the posttest, but not to a statistically significant degree. In line with the results in Chan and Liou's study (2005), the concordancing effects lasted until the delayed posttest.

The Quantitative Approach in Computer-Assisted Language Learning Studies

The TSD allowed us to observe our students' development of English vocabulary over seven months repeatedly and to establish the effects of the concordancing instruction. Such a design is valuable as an exploratory, hypothesis-generating investigation. However, because of the small number of the participants resulting from the intensive nature of TSDs, our findings have limited generalizability (Mellow et al., 1996).

The statistical tests illustrated above are nonparametric. Several nonparametric tests like the Friedman test and the Wilcoxon signed-rank test only preserve information about the order of the rank and ignore the exact values. Some information about the data is lost. Therefore, nonparametric tests produce less information than parametric tests and are less powerful in testing hypotheses concerning the probability of reaching significant differences (Book, 1977; Dörnyei, 2007). Still, nonparametric tests can apply to a wide variety of data which are nominal and ordinal as well as interval. Besides, unlike parametric tests, they

make less stringent assumptions of data, such as the shape of normal distribution and homogeneity of variance. No matter what the size of observation samples is, nonparametric tests can still be applied (Hatch & Lazaraton, 1991; Weiss, 2002).

Together, TSDs and nonparametric statistical tests combine to provide computer-assisted language learning (CALL) researchers with a powerful approach with which to trace the linguistic development of small samples of CALL users during their schooling.

This entry was partially funded by the Taiwan National Science Council (NSC 96-2411-H-007-033-MY3).

Technology and Listening

PHILIP HUBBARD

As one of the four core skills, listening plays an important role in most modern language teaching methodology. Morley (2001) recognizes four general models for listening activities: listening and repeating; listening and responding to comprehension questions; task listening, where the learner processes spoken language in order to achieve some other objective, such as following directions on a map or taking notes; and interactive listening, where the learner switches between the role of listener and speaker as in small group discussions. Listening has long been linked to technology for recording and broadcasting the human voice, and each of the preceding models has been implemented using relevant technologies. The phonograph, audio and video tape (the former especially linked to the language laboratory), radio, television, and the telephone have all provided tools for enhancing the availability of opportunities for listening. Most recently, however, digital technology in the form of DVDs, CD-ROMs, and files played, streamed, or downloaded from the Web have allowed for a new range of interactivity with recorded material. Internet voice and video applications like Skype (www.skype.com) allow for listening and speaking integration in natural communicative activities, with the added option of text-based chat for clarification.

History

In terms of computer technology, a breakthrough in listening for language learning was the laser videodisc in the 1980s: it allowed the listener to use such features as random access, captioning in the native and target language, multiple soundtracks, annotations, glossary support, and links to comprehension checks. The 1980s also saw audio capabilities appearing in personal computers: a leader in this revolution was the Apple Macintosh with its built-in sound system—disc-based listening programs were developed for it using Apple's HyperCard authoring application. As CD-ROM drives became common on computers in the 1990s, there was a rapid growth in commercial language learning programs employing multimedia in the form of integrated text, sound and animated graphics, many of which claimed to represent a complete language learning solution and included listening as one of the skills.

Although video could be saved on and played from early CD-ROMs, the amount of material one CD could hold was notably limited. The invention and rapid spread of DVDs beginning in the mid-1990s added a new set of options for listening. Like the laser videodisc, the DVD allowed for random access of digitally stored material including not only the video but alternate synchronized sound tracks. Over time DVDs came to displace VHS tapes as the cost of both disks and their players dropped and made them accessible for widespread institutional use.

Beginning in the late 1990s, the greatest changes in listening have occurred due to the spread of audio and video files on the World Wide Web. Along with CD-ROMs and DVDs, the Web has impacted the teaching and learning of listening in the following areas: availability of and access to a broad range of current materials, inclusion of first language or

target language text, presence of lexical support and other annotations, the listener's control of the speech signal, and the listener's manipulation of the speech signal. Some of these features have been the subject of research studies while others have appeared in practice-based literature.

Listening Materials

In terms of listening materials, there is an enormous—and growing—supply available in both commonly taught and many less commonly taught languages that can be used by teachers in class or laboratory settings or by learners working independently. Besides audio and video materials on CD-ROMs, DVDs, and the Web, there are also portable formats, podcasts and vodcasts, for audio and video respectively, for handheld devices like MP3 players and smart phones. Some of these are dedicated listening materials developed specifically for the purpose of language learning, including both teacher-created and commercial language software products and supplementary resources from language textbook publishers to accompany their print materials. There are also many sources of authentic, native speaker materials on the Web. Some of these can be accessed from sites that provide dedicated language learning support (added transcripts, subtitles, annotations, glossaries, and quizzes) to make the authentic material more accessible to learners. More commonly, authentic materials may include just text support in the form of subtitles or transcripts for the assistance of the hearing impaired, which can also be useful for language learners. Google's advanced video search (<http://video.google.com/videoadvancedsearch>) not only allows the user to limit the search to a particular language but also to look specifically for captioned videos. While it is true that the majority of authentic materials, especially those on popular free sites such as YouTube (www.youtube.com), are accompanied by no text support, they can still be valuable to learners at a level advanced enough to comprehend them to a degree.

As noted above, materials with some form of text support can be found for many languages. Subtitles (or captions—the two will not be distinguished here), which can appear in either full or keyword versions and in either the first or second language, can increase comprehension and make it possible to link the spoken language to more familiar or salient forms. Online transcripts of both audio and video offer advantages similar to those of subtitles, but with the added potential of linking directly to online glossaries or dictionaries (e.g., www.babylon.com). The addition of target language text support not only assists comprehension but improves the potential for acquiring new words and phrases or reinforcing those already partially learned (Danan, 2004). This is because it is often difficult for learners to isolate individual forms from the speech stream so that they can be attended to and singled out to reflect on or to look up in a dictionary afterward. Furthermore, text support can help with phonological processing of word boundaries and reduced forms. Although transcripts have always existed for some audio material, and captioning was available on many VHS videos and still is on a lot of broadcast television shows, their wider availability online today makes them more natural elements of the language learning environment.

Listening With Text Support

Evidence from a number of studies suggests that listening with text support can be helpful in subsequent nontext-supported listening in both the short and long term as well as in incidental vocabulary acquisition (Danan, 2004). Markham and Peter (2002–3) showed that both first language and target language subtitles helped students of Spanish with a subsequent unsubtitled listening comprehension assessment compared to students who

had viewed preliminary material without subtitles, further noting that first language subtitles were more effective for this particular group than target language subtitles. Guichon and McLornan (2008), while also acknowledging the value of both L1 and L2 subtitling, noted that L1 subtitling may cause more lexical interference.

In a comparison of subtitles and transcripts, Grgurovic and Hegelheimer (2007) addressed the question of whether students engaged in listening comprehension tasks where both subtitles and transcripts were available would use one more than the other. Using tracking data, they concluded that for the group as a whole subtitles were used significantly more frequently. However, some individuals preferred transcripts. Beyond improving comprehension and supporting vocabulary development, Borrás and Lafayette (1994) demonstrated the impact of listening with subtitles on subsequent oral language tasks: students controlling subtitles in a French video through a computer program outperformed students who did not view the video with subtitles. Finally, Hulstijn (2003) provided arguments based on connectionist theory for presenting listening activities with delayed text support and described an application that uses this feature along with “chunking” input using pauses between utterance fragments to promote more automaticity in bottom-up processing. While the preceding research demonstrates the value of text support in the classroom setting, Vandergrift (2004) cautions that listening practice with text support does not properly prepare learners for the reality of processing real-time connected speech.

Another area of interest in technology in listening is the question of how computer-based lexical support can influence comprehension and acquisition of vocabulary. As noted, one of the features of text support is that it allows the isolation of lexical forms, which can then be linked to either a dedicated glossary or electronic dictionary. Jones and Plass (2002) showed that for beginning French students, both text recall and vocabulary learning were better with combined pictorial and text annotations, and that on a delayed posttest, the pictorial influence was stronger. Xu (2010) reviewed the literature on the impact of multimedia vocabulary annotations on incidental vocabulary learning and comprehension for both reading and listening. He concluded that for listening, there were mixed results regarding the superiority of multimedia over single mode annotations (picture or text alone) for vocabulary acquisition, but that there is convincing evidence that annotations with picture and text together improve comprehension, and the effect is stronger when collaboration is allowed. Other research has explored the degree to which students use these supports when offered them: Hegelheimer and Tower (2004), for instance, found that few students in their study used the textual gloss option during a listening activity.

Manipulation of Aural Language

Another application of technology relevant to listening comprehension and language acquisition is in the control and modification of recorded speech. At the level of control, modern digital media players offer all the features that analog tape players did and more. In addition to a time marker, pause, fast-forward and rewind controls, there is typically a “playbar” with a slider allowing the user to move rapidly from one part of an audio or video to another. Some players, such as the VLC player (www.videolan.org/vlc), additionally include keyboard controls that allow the user to jump back a set amount (e.g., two seconds), arguably a useful feature for language learners wishing to repeat a string they just heard. Besides control, it is possible to use technology to modify characteristics of the speech signal. For example, some players come with graphic equalizer controls, allowing the user to change the relative strengths of the frequency ranges in the audio or video to optimize them for human speech.

Perhaps the most intriguing modification, however, is to the speech rate. Unlike phonograph records and audio and videotapes, digital speech signals can be slowed (or accelerated) in the time domain without changing their frequencies, thereby maintaining

4 TECHNOLOGY AND LISTENING

a more natural sound even when slowed. Several media players have this feature. Although early research on slower speech showed no consistent advantages to it, Zhao (1997) found that students who were allowed to control the speech rate, slowing it as desired, outperformed those who had no control on comprehension measures. Jensen and Vinther (2003), though not allowing student control, concluded that slower speech seemed to influence students' noticing of grammatical forms. In both cases, the speech rates were preset (slow and fast) by the researchers. Further research is clearly needed in this area now that users can readily control the degree to which speech can be slowed or accelerated.

Learner Control

Finally, a key theme found in studies on a range of topics related to listening and technology (Zhao, 1997; Hoven, 1999; Grgurovic & Hegelheimer, 2007) is that learner control or choice is an important factor. This may include choice of listening task, choice of materials, choice of supports, or choice in the path through the listening activity. Rost (2007), for example, recommends giving the user control over input speed, pausing, and replay functions. Control alone does not necessarily provide a positive outcome: Roussel, Rieussec, Nespoulous, and Tricot (2008), who tracked student use of pause, rewind, and fast-forward functions with French students listening to German MP3 audio files, noted differences in their use patterns. More competent students listened holistically and less competent ones paused more often. The ability to make informed choices as to which controls and supports to use and when to use them has been argued to be enhanced by dedicated learner training (Hubbard, 2004).

Theoretical Perspectives

In addition to the research base, several attempts have been made to look at digital listening from a more comprehensive theoretical point of view. Hoven (1999) proposed a learner-centered model for multimedia listening integrating sociocultural methodological principles (mediation, goal-oriented learning, zone of proximal development, and community of practice) with listening comprehension processes and texts, instructional design criteria, and learner features. Chapelle (2003) drew on hypotheses within the interactionist perspective, sociocultural theory, and depth of processing theory to suggest how language acquisition can be promoted when the interaction is between human and computer rather than human and human. For example, she proposed that assistance provided by a computer program on request, such as translation, definitions, simplification, elaboration, repetition, and highlighting, represent modified input that can make meaning more comprehensible and forms more salient. More recently, Plass and Jones (2005) have proposed a multimedia model combining Mayer's cognitive theory of multimedia and Chapelle's application of the interactionist perspective of second language acquisition to computer-assisted language learning. In their model, which appears applicable to listening to video as well as using multimedia glossing for lexical development, visual and linguistic input is integrated in a dual-coding process that makes comprehensible input more likely to become intake for language acquisition.

Assessment of Listening

Besides its potential for improving listening skill instruction and language acquisition through the aural modality, computer technology can also be used for language assessment, where the computer's ability to deliver consistent audio and video quality, maintain

time control, record student responses, and even automatically score them, can add to the reliability and efficiency of the assessment process. In addition to classroom uses, computer-based assessment for listening proficiency and placement is occurring in institutional settings and in commercial tests, such as the TOEFL iBT (Internet-based test of English as a foreign language). Additional possibilities include adaptive testing of listening to increase assessment efficiency and drawing appropriately leveled items from a larger pool to construct individualized tests. Looking at student behavior during multimedia listening tests, Wagner (2007) found that contrary to previous claims that students focused on their test papers and failed to make use of the visual channel, test takers in his study spent the majority of their time (an average of 69%) orienting to the video although they oriented to it more during a dialogue sequence than a short lecture.

Future Directions

If there is one thing we can predict for the future, it is that technology for listening will continue to evolve. But beyond the technology, we can expect the research and methodology base in this area to keep growing as we develop more sophisticated techniques and strategies for interacting with digital materials through the skillful use of text support, hypertext-linked glossaries and dictionaries, and manipulations like speech rate control. Robin (2007) predicted that in the next five to ten years, effective use of these along with translation bots and interactive voice chat will make it possible for learners from a broad range of learning styles to experience a much wider range of input at an appropriate level than has previously been the case, or than would be possible with off-the-shelf software.

Based on present trends, we can also anticipate expansion in the range and availability of options for mobile listening, through smart phones and other handheld devices, as well as interactive listening and speaking experiences in virtual worlds like Second Life. Outside of the occasional language classroom that still relies on audio and VHS cassettes, it is becoming increasingly rare for language students to draw their listening experiences from analog recordings. Perhaps even more important, when listening to recorded material, whether on podcasts, DVDs, streamed lectures and television shows, or YouTube or other online videos, listeners of all kinds have access to the same media controls and text support that are useful for language learning. In this digital era, then, the listener has more command over input than ever before. Thus, in allowing learners to use these controls and supports—and even training them in how to use them effectively to the degree we can—we are not just providing scaffolding, we are preparing them for future authentic online listening experiences beyond the classroom.

Despite the promise of these new technologies, recent texts on listening theory and methodology (Flowerdew & Miller, 2005; Field, 2008) include little discussion of their unique properties as aids to listening comprehension and language acquisition through the aural channel, suggesting that computer-based listening of all sorts has not yet made it into the methodological mainstream. To date there have been no monographs or edited volumes on the topic, although there was a 2007 issue of the online journal *Language Learning & Technology* (<http://llt.msu.edu/>) devoted to the theme of technology and listening comprehension. It seems evident that this is an extremely productive area of inquiry for future applied linguists.

Technology and Literacy

DENISE E. MURRAY

For centuries, scholars and governments have both decried the introduction of new technology as a destroyer of societal values and promoted it as responsible for civilization advances. Taking a diachronic perspective on literacy-related technologies, this entry demonstrates that such technologies are grounded in the ideologies of their contexts of use.

Defining Terms

Because both literacy and technology are contested terms the position taken here is discussed. Technology will refer to any item that extends human capacity, thus including technologies as diverse as eyeglasses, chalk, writing, telephones, and computers. What is meant by literacy is more controversial. Traditionally, it has been defined as the ability to read and write. For example, the 1958 UNESCO definition was “a literate person is one who can, with understanding, both read and write a short simple statement on his or her everyday life” (UNESCO, 2004, p. 12). After much criticism, failures of UNESCO-sponsored literacy campaigns, and ideas from literacy scholars, in 2003 UNESCO determined that “Literacy is the ability to identify, understand, interpret, create, communicate, and compute, using printed and written materials associated with varying contexts” (UNESCO, 2004, p. 13). This definition still does not take a critical approach, which involves questioning and challenging dominant ideologies.

Defining literacy in terms of reading and writing, even taking a critical perspective, does not encompass all of the ways people use semiotic systems. Many other systems have been attached to the term literacy—media, computer, visual, information, financial, scientific, and cultural. Written literacy has itself been subdivided into basic, functional, and print literacy. Literacy is not one skill set for one purpose; rather, there are multiple literacy practices, depending on the context and purpose of the literacy event. Literacies are intimately woven into the fabric of sociocultural practices of thinking, valuing, believing, and interacting. “There can be no disinterested, objective, and value-free definition of literacy: The way literacy is viewed and taught is always and inevitably ideological” (Auerbach, 1991, p. 71). Street (1995) therefore differentiated between the autonomous (skills such as word attack skills, sound-symbol relationships, or letter recognition) and ideological (shared values attached to literacy practices) dimensions of literacy.

As new literacy technologies have developed, the powerful with expertise in the old technologies claimed that they thwarted and limited human capacity rather than extending it. Underlying this ostensible reason for resisting the new technologies was their concern about *whose* human capacity might be extended and *whose* power might be restricted. To illustrate, this entry will focus on four eras—Ancient Greece, Medieval Europe, the printing press, and the information age.

Literacy Technologies

Writing systems developed independently in Mesopotamia (3000 to 2000 BC), China (1200 BC), and Mesoamerica (400 BC). Many scholars cite Greece as the origin of an

2 TECHNOLOGY AND LITERACY

alphabetic system, while others claim the Greek alphabet was an adjustment to that of the Phoenicians.

Ancient Greece

Both Socrates and his student Plato were less bothered with autonomous literacy than with ideological literacy. They were concerned with what people did with the information gained through literacy, condemning the move from oral to written language because it would disrupt the social status quo. For Plato, only the elite should have power and making writing available to others was disruptive, “once a thing is put in writing, the composition . . . drifts all over the place, getting into the hand not only of those who understand it, but equally of those who have no business with it” (Hamilton & Cairns, 1989, p. 521). Furthermore, writing gave people only the appearance of wisdom. In the *Phaedrus*, Plato used the parable of King Thamus in Egypt to criticize writing because of the effect it had on memory:

this invention will produce forgetfulness in the souls of those who have learned it. They will not need to exercise their memories, being able to rely on what is written, calling things to mind no longer from within themselves by their own unaided powers, but under the stimulus of external marks that are alien to themselves. (Hamilton & Cairns, 1989, p. 520)

For Plato, the essence of human communication was in the dialogic. The “Socratic method” forced speakers to analyze their own ideas so that the only sustainable ideas are those that the speaker can “reflectively defend in face-to-face dialogue with someone else” (Gee, 1996, p. 27).

Yet literacy scholars have claimed that the invention of writing was the invention of a new technology of the intellect (Goody & Watt, 1968) that shapes the way we understand the world and ourselves (Olson, 1994). They and others claimed that the change from oral to written cultures led to changes in intellectual development, such as logical, objective thinking, and challenging tradition, with alphabetic writing being particularly influential because of its abstract representation of sounds. Alphabetic writing contrasted with previous writing systems such as pictograms, logograms, and Chinese because they are difficult to use, leading to only an elite being in possession of the skills and associated power. Alphabets, on the other hand, are democratic.

Medieval Europe (AD 500 to AD 1440)

Medieval Europe had rich written manuscripts, but the province of written literacy was restricted to scholar-priests, royal bureaucrats, or secretaries, who, as holders of knowledge, held great power. Most formal uses of literacy were in Latin, Greek, or Arabic (depending on the part of Europe), not the local vernacular. By the 13th century, literacy had spread to record keeping in business and lay education for students not intending to become religious, and in England the Lollards, dissidents challenging the power of the Catholic Church and its monopoly on reading and interpreting the Bible, published their tracts in the vernacular.

The general population, however, had highly developed visual literacy, depicted in stained glass windows, paintings marking the Stations of the Cross, or icons. Interestingly, although Islam’s holy book was also in writing, because Islam did not permit representations of human beings, mosques were decorated with religious texts. Consequently, believers needed to be able to read Koranic texts, resulting in the Koranic school tradition where Muslim boys learned to read. However, the reading was primarily rote memorization, with only the appearance of reading, with these boys not able to use their literacy for other

purposes (Ferguson, 1971). Similarly, the religious of Medieval Europe, although some were able to read for meaning when scribing, did not for fear they would inadvertently write their own interpretation of holy texts, rather than replicate them.

The Printing Press

The printing press allowed texts to be reproduced in quantity and to be fixed forms of reference, leading to indexing. However, early printed texts replicated scribal manuscripts, with the same illuminations, page layouts, and letter shapes. The church hierarchy took a dim view of the ordinary person having access to the Bible without the intervention of trained clergy to interpret it. Pope Alexander VI, for example, declared “It will be necessary to maintain full control over the printers so that they may be prevented from bringing into print writings which are antagonistic to the Catholic faith” (quoted in McCorduck, 1985, p. 23). In Britain, unorthodox ideas were circulated in printed books in English, leading to a 1536 act of parliament preventing women and lower classes from reading the Bible (Lawson & Silver, 1973).

Social historian Eisenstein (1979), on the other hand, considers that the printing press positively transformed society. It freed cognitive functions from memorization so they could be used for thinking, such thinking leading to the Reformation and the Renaissance. With more texts available, scholars could compare ideas and formulate new ways of thinking. With vernacular language structures fixed through print, nationalism could evolve. McLuhan (1962), who popularized this view of the printing press, credited it with the rise of science, industry, logic, capitalism, nationalism, and rationalism.

The Information Age

Both synchronous and asynchronous modes of ICT communication involve different configurations of the autonomous and ideological dimensions of literacy. Moreover, the various uses of ICT literacies have also been excoriated. Ong (1982), echoing Plato, said that “[w]riting is passive, out of it, in an unreal, unnatural world. So are computers” (p. 79). Others attribute positive changes in society to ICT. Others are concerned that online communities and social networks may replace offline communities and social networks as people isolate themselves in front of their computer terminals, rather than interacting with friends and relatives face-to-face (Kraut et al., 1998). However, for most people, computer-mediated communication is an extension of their social interactions (McLuhan, 1994), another tool in their repertoire of communication (Murray, 1991).

Synchronous modes include chat, instant messaging (IM), and texting (SMS). Chat was invented prior to e-mail, which only became possible once store and forward was developed, allowing asynchronous communication. Chat did not capture the imagination of the general public, but e-mail did, largely because it is asynchronous and did not have a limited number of characters (Murray, 1991). Today, three of the most popular communication modes have a restricted number of characters—texting, chat, and Twitter.

In Twitter, the two most common words are *the* and *I*. While the former is the case for other written material, the use of *I* is a result of the sociocultural literacy practice of Twitter. Men have more followers than women, the reverse of other social networking sites; “Twitter resembles more of a one-way, one-to-many publishing service more than a two-way, peer-to-peer communication network” (Heil & Pisorski, 2009).

Texting is “bleak, bald, sad shorthand. Drab shrinktalk . . . Linguistically it’s all pig’s ear . . . it masks poor spelling and mental laziness. Texting is penmanship for illiterates” (John Sutherland, quoted in Crystal, 2008, p. 13). However, the simplified register used in texting is not new, nor does it hinder literacy. Just as in e-mail and chat, texters accommodate language to their context. Not all texters use abbreviations or other grammatical

4 TECHNOLOGY AND LITERACY

or orthographic devices (Thurlow & Brown, 2003; Ling & Pedersen, 2005). Furthermore, texting has caught on around the world among adults as well as teenagers.

The most popular asynchronous mode is e-mail, initially the province of propriety companies and universities. Even so, fax was more widely used, largely because the technology was not very different from ones people already knew—the telephone and the photocopier (Murray, 1995). In the late 1990s, e-mail became popular, with more user-friendly interfaces and more people having access to computers at work or at home. More recently, with cell phone access, e-mail has continued to gain in popularity, but not to the extent of texting and IM, largely because many people use cell phones for such access and typing words without QWERTY keyboards is tedious.

Recently John Freeman (2009) condemned e-mail:

It has put us under great physical and mental strain, altering our brain chemistry and daily needs. It has isolated us from the people with whom we live, siphoning us away from real-world places where we gather. . . . It has made it more difficult to read slowly and enjoy it, hastening the already declining rates of literacy.

Approaches to the Effects of Technological Innovations

Scholars have posited two different theories concerning the introduction of new technologies. The deterministic model claims that the technology inevitably leads to changes in human thinking and behavior. The social shaping of technology (SST) model holds that the technological innovation finds acceptance and diffusion occurs because of the sociocultural values and needs of the time.

Technological Determinism

From this perspective, technology develops without reference to outside forces and socio-cultural practices, as McLuhan (1962) and others claimed for printing. The progression is linear, inevitable, and the new replaces the old; it affects society and changes it.

[N]ew technologies are discovered, by an essentially internal process of research and development, which then sets the conditions for social change and progress. Progress, in particular, is the history of these inventions, which “created the modern world.” The effects of the technologies . . . are as it were the rest of history (Williams, 2005, p. 5).

The technology of literacy has been a prime example of technological determinism through the long tradition of ascribing cognitive consequences to literacy.

Those who reject new literacy technologies also take a deterministic point of view because their claim is built on the premise that the new is inevitably destroying society and its values. In the examples of the different literacy technologies discussed above, both sides of technological determinism are actually arguing over “issues of power and control—over form, authorship, distribution of knowledge, and the very construction of knowledge itself” (Murray, 2000, p. 44).

SST

An alternative reading of the influence of new technologies examines them in their context. From this perspective, sociocultural precursors to the technological innovation facilitate its acceptance, and the technology amplifies certain sociocultural characteristics (or not). In discussing media literacy, Lewis and Jhally (1998) noted: “a textual analysis which takes

place without examining the institutional, cultural, and economic conditions in which texts are produced and understood is necessarily limited. It [media literacy] is about an awareness of why those messages are there" (p. 111).

Despite the railings of Plato and claims of a literate culture in fifth-century BC Greece, it was still primarily an oral culture, with political and legal proceedings being conducted in spoken language. Literature too was read aloud. Furthermore, alphabetic literacy, rather than being the cause of scientific thought and reasoning, amplified ways of thinking already valued. The Greeks already valued language, whose characteristics they objectively critiqued and played with for humor such as in plays on words. Both wit and rhetoric were used with skill. Further, claims that the alphabet caused syllogistic reasoning are unfounded because such reasoning also developed in India and China, neither of which had alphabetic writing systems (Gough, 1968).

Similarly, in Medieval Europe oral language was the primary form of communication, with even written books being read aloud. Even after print materials became available, people continued to memorize large quantities of text. These practices continued because of the value they held for the particular societies. In Medieval Europe the "spread of reading and writing skills had created a market for books, and the economic systems of the late Middle Ages predisposed industrious businessmen like Caxton and Gutenberg to fill a need where they saw one" (Pattison, 1982, p. 99). The success of printed texts was not the result of Gutenberg's invention, but of the sociocultural practices of the time. Although not universal, literacy was sufficient to support print production. Protestantism promoted individual understanding of the Bible; so the reformers in Germany and elsewhere encouraged literacy. The Protestant reformers themselves were reflecting changes in social values already taking hold in Europe—individualism, nationalism, and secularism.

The invention of the computer also co-occurred with major changes in global trade and diplomacy. Each of the ICT literacies found a niche that resonated with existing and emerging sociocultural practices. With global trade, for example, asynchronous modes became vital for communication across time zones.

Texting became popular because it is unobtrusive and permits privacy in public settings, compared with talking on a cell phone, and it can be more direct, allowing communicators to dispense with the phatic communication required in spoken communications. However, in the United States, because computers were ubiquitous, e-mail became more popular, compared with in Europe (Naomi Baron quoted in Crystal, 2008, p. 98).

Despite the dire predictions of those who take a negative deterministic perspective, most texters understand the needs of their audience and know when to choose which language variety for which purpose and which audience (Crystal, 2008). Furthermore, a recent Pew study of the Internet and mobile phone use in the United States (Hampton, Sessions, Ja Her, & Raines, 2009) shows that people have not become more isolated, but have larger and more diverse discussion networks.

An Ideological Perspective

"*Nothing* follows from literacy or schooling. Much follows, however, from what comes *with* literacy and schooling . . . namely, the attitudes, values, norms, and beliefs" (Gee, 1991, p. 280) that shape literacy practices in the culture in which it is used. Mackay and Gillespie (1992) suggest extending the SST model to include the ideologies that shape the technology. They argue that designers and marketers play roles in this shaping—but not deterministically because users appropriate the technology for their own purposes, as with the inventions of the telephone and wireless. For example, the telephone's appropriation led to socio-cultural practices such as "the protocols of voice mail, the ubiquitousness of telemarketing,

or the use of a telephone number as identification" (Murray, 2000, p. 51), or as a third party in face-to-face interactions when people text during dinner or meetings. Similarly, Babbage and Alan Turing might be surprised that their computational machine became a social networking tool. A technology that was introduced to facilitate business and an application designed for military research (the Internet) were co-opted for personal communication. As Kaestle reports concerning the technology of literacy,

Princeton historian Lawrence Stone once remarked that if you teach a man to read the Bible, he may also read pornography or seditious literature; put another way, if a man teaches a woman to read so that she may know her place, she may learn that she deserves his. These are the Janus faces of literacy. (Kaestle, 1991, p. 27)

From an ideological perspective, these are the Janus faces of technologies.

Conclusion

Changes brought about by the introduction of new literacy technologies are the result of complex sociocultural imperatives. The technologies either impede prevailing and emerging sociocultural values or amplify them. If the former, the technology is not extensively adopted; if the latter, the technology is embraced in the service of those sociocultural values it can amplify. These different technologies adapt language and each focuses on particular linguistic choices that are best suited to the technology.

Technology and Phonetics

REBECCA HINCKS

Sound cannot be studied methodically unless it can be captured in some way, and so from the phonograph to the tape recorder to the computer, the development of new technologies has facilitated the study of phonetics. Indeed, it is difficult to imagine studying phonetics without technology. Other entries in this encyclopedia discuss the topics of acoustic phonetics, speech analysis software, automatic speech recognition, text-to-speech synthesis, and computer-assisted pronunciation teaching. This entry will thus simply provide an overview of the position of technology in phonetics.

Major contributions to the understanding of speech have been made by researchers whose basic training was in science or engineering. Scientists and engineers have developed systems for analyzing the acoustic signal, and for transforming text to speech and vice versa. The developments of these technologies have been motivated by the desire to perform basic research in speech production and perception, but also for more practical purposes; for example, to develop aids for people with different types of sensory and physical disabilities, to create effective and natural speech-based computer interfaces, or to provide valuable pronunciation feedback to second language (L2) learners. The necessity for creating systems with practical applications can serve as a catalyst for insights into spoken language itself (Greenberg, 2001).

The study of phonetics is traditionally divided into three areas: *acoustic phonetics*, the study of the speech signal itself; *articulatory phonetics*, or how we produce speech using our vocal tract; and *auditory phonetics*, or how we hear and perceive speech.

Technology and Acoustic Phonetics

When people think about technology and phonetics they may first think about *speech analysis software*, which is used to visualize and manipulate sound. The benefits of this technology were once restricted to those who could buy relatively expensive software, but the advent of freeware/shareware for speech analysis now allows anyone with a computer to work with sound files in multiple ways. The features of these programs vary, but all provide at least a waveform, spectrogram, and display of fundamental frequency. A well-maintained, versatile, and widely used downloadable system is Praat (Boersma & Weenink, 2008); another is WaveSurfer (Sjölander & Beskow, 2010), which is open source.

Language teachers and linguists should be familiar with the capacities of these programs so that they can use them to teach and do research in pronunciation (Levis, 2008). For example, a study of regional variation in vowel production could be enhanced by actually measuring the formant frequencies of the respondents' productions (Palmstierna, 2007). A study of nonstandard question formulation in the lingua franca environment could use pitch tracings to see whether final-rising question intonation was actually being used (Björkman, 2010). Students having difficulty perceiving the difference between long and short vowels could look at spectrograms of their productions, comparing them to models, so that visual information could support the missing auditory information (Wik & Hjalmarson, 2009). These are just a few examples where a basic use of speech analysis has improved the quality of teaching and research. Work has also been done with applying speech

analysis in new ways. Hincks and Edlund (2009) gave feedback on the standard deviation of fundamental frequency to Chinese first language (L1) speakers of English in a successful effort to get them to speak with more pitch variation in an oral presentation situation.

A second important technology in phonetics is *speech synthesis*, also known as text-to-speech (TTS). Here major roles have been played by engineers, for example Gunnar Fant, whose basic training was in electrical engineering. His source-filter theory of speech production (Fant, 1960) models the larynx as a source of sound energy, and the vocal tract as a filter shaping the phonemes. The source-filter theory was used to develop the first parametric (rule-based) TTS synthesizers, among them PAT (developed at MIT by Walter Lawrence), OVE I, and OVE II (Klatt, 1987). Parametric synthesizers are still used today in research because of their flexibility, but techniques that concatenate (chain together) fragments of recorded human speech (Hunt & Black, 1996) have been able to achieve more natural-sounding speech synthesis. Recent developments in speech synthesis focus, for example, on adding a visual component by integrating the synthesis with an embodied agent, or talking head (Beskow, 2003; Massaro & Light, 2004) or with a model of the vocal tract (Engwall & Balter, 2007). It is hoped that these developments will provide a richer environment for pedagogical applications of speech technologies, such as speech training for the hearing impaired and L2 pronunciation training.

A third major speech technology is *automatic speech recognition* (ASR). Speech recognition is not to be confused with voice recognition, or speaker recognition, the purpose of which is to identify a person by the sound of his or her voice. ASR systems can be built to recognize a large number of different speakers using a relatively limited vocabulary, or for a single speaker with a large vocabulary. The last decade has brought much progress in the accuracy of ASR for English, particularly for speaker-dependent dictation systems. Dictation software can now be used to speed up the process of transcribing monologue (Hincks, 2010). Caution should be used, however, when trying to use dictation software on accented speech.

ASR is a key component of *dialogue systems* for communicating with computers, but it is only the first step in the process. In order for the computer to be able to respond to the speech input, it must also shape some kind of understanding of the message using another technology: natural language processing. Many applied linguists would welcome the creation of intelligent and natural dialogue systems that could also respond to the accented speech of an L2 learner, allowing the learner to have a “conversation” with the computer. This achievement would be a bonanza for those who believe in communicative language learning as opposed to the drilling exercises for which computers are most naturally suited, but these research objectives have yet to be met truly successfully.

Technology and Articulatory and Auditory Phonetics

Phoneticians studying articulation are aided by a variety of techniques for producing images of the hidden generation of the sounds within the vocal tract. Early work used X-rays to film subjects producing sounds in real time; now safer techniques such as magnetic resonance imaging are used. Using electropalatography, or a prosthetic palate containing electrodes, phoneticians can study the contact between the tongue and the palate. Data regarding the movement of visible features such as the lips and face can be gathered using motion capture, wherein subjects wear markers whose movement is detected by a special camera. This information can be used to create animated faces that can be displayed producing recorded or synthesized speech, providing important visual support to the auditory message.

The study of auditory phonetics has a strong connection to the telephone industry, so that the telephone signal can be shaped to transfer the sounds that perception most relies on. Within auditory phonetics, speech signal processing has enabled auditory phoneticians to develop hearing aids and cochlear implants for the hearing impaired.

Current Research Challenges for Speech Engineers

The annual Interspeech conference, run by the International Speech Communication Association (ISCA), attracts over a thousand full-paper submissions on speech research. The papers address issues in speech production and perception as well as new techniques for speech technologies. Within ASR, researchers work, for example, on how to recognize larger vocabularies, and speech in noisy environments. Many papers address prosody and emotional speech, with the aim of improving the naturalness of TTS and the ability to recognize prosodic contributions to meaning in speech. Speech translation technology is a topic of recent interest, as is the possibility of conducting searches in spoken documents. Computer-assisted pronunciation training needs to be improved by the creation of more meaningful feedback, which not only detects deviations in pronunciation but tells the student how to correct them. The study of discourse and dialogue has its own special interest group within ISCA (SigDial), as does the field of speech and language technology in education (SLaTE). Those applied linguists whose background is more within the social sciences than the hard sciences should not hesitate to explore the literature published by ISCA and journals such as the *Journal of Acoustical Sciences* and *Speech Communication*.

Technology and Phrases

GILL PHILIP

Like many linguistics terms, “phrase” also has a nontechnical use in the general language. We notice and comment on (especially unusual) “turns of phrase”; most of us at some time in our lives have asked for help in “how best to phrase” a request or a letter; and, when travelling, we often make use of foreign phrase books. Rarely does it occur to us to define what we mean by “a phrase,” or to wonder why phrases are sometimes more useful to us than single words are. This entry explains what phrases are and provides an overview of the most common phrasal types. It also discusses some of the ways in which phrases can be identified and retrieved automatically and semi-automatically from computer language corpora.

What Is a Phrase?

According to Gries (2008), a “phrase” consists of two or more word forms which together express a semantically complete meaning. The words may undergo morphological variation (in most phrases), and usually occur in an established sequence. This definition is maximally inclusive. Phrases encompass a heterogeneous range of linguistic structures including idioms (*throw caution to the wind*), proverbs (*too many cooks spoil the broth*), conventionalized similes (*as dead as a dodo*), quotations (*to be or not to be*), sayings (*if you can’t beat ‘em, join ‘em*), catch-phrases (*here’s one I prepared earlier*), formulaic greetings (*how do you do*), phrasal verbs (*set up, look into, get away with*), and complex prepositions (*in order to, on behalf of*). Some, such as *by and large* or *for the most part*, are completely frozen, meaning that the word forms and their sequencing are always the same: No inflected forms or additional elements are allowed, and no inversion of the words is possible.

Frozen phrases are very much the exception to the rule. The *canonical form* of a phrase, normally used as its citation form in dictionaries and other reference works, is in fact only one of its possible realizations, albeit typically the most commonly occurring one. Phrases bend to the will of the textual environment in which they are used: verbs inflect for number and person, tense and aspect (though change to verb mood is much rarer); personal pronouns have to agree with their grammatical subjects and objects; nouns are pluralized and attract modifiers; prepositions are altered so that they reflect grammatical relations more appropriately. Phrasal verbs belong to this middle cut of phrasal types: Their verbal component has full inflectional capabilities (*give up, gives up, gave up, given up, giving up*), and the verb’s direct object can interrupt the phrasal sequence (*take off; take it off; take your coat off*). Phrasal verbs aside, many phrases contain a variable slot, often for a direct object, as in *bear something in mind*; or a possessive pronoun, as in *shake in one’s shoes*.

To complicate matters further, some phrases appear not to have a canonical form at all, and indeed may not even require any single lexical item to be present. Instead they consist of a lexicogrammatical configuration which combines aspects of syntax and semantics in a more abstract manner. One such phrasal type is the *semi-prepackaged phrase*, which can be illustrated with *the faintest idea*, and its variants (Francis, 1993, p. 144). *Faintest* can be replaced by any superlative adjective denoting indefiniteness (including *least, slightest*,

remotest, foggiest), while *idea* can be replaced by any noun belonging to the same semantic set (e.g., *conception, notion*); yet not one of these single words is essential for the meaning to be conveyed successfully. Another kind of phrase which has no canonical form is the *idiom schema* (Moon, 1996). This differs from the semi-prepackaged phrase in that it features a central metaphorical conceit which provides the motivation for the meaning conveyed. Idiom schemas can exploit semantic sets in the realization of their variant forms, allowing content words to be replaced by others with a similar semantic content (e.g., *quake/tremble/shiver* in place of *shake* in *shake in one's shoes*), but ultimately the conceit takes precedence. The schema [numeral + hyponym + *short of a(n)* + superordinate] with its underlying conceit of incompleteness can be realized as *one sandwich short of a picnic, several cards short of a full deck, a few gallons shy of a full tank*, all of which are interpreted to mean “slightly crazy” (Moon, 1996, p. 252).

Identifying and Extracting Phrases Using Technology

Fully Automated Methods of Identifying and Extracting Phrases

The inherent plasticity of phrases poses problems for computational approaches to phraseology, with the result that at present, the fully automated identification and retrieval of phrases from computer language corpora have still not been achieved. This does not mean that phrases and other recurrent word sequences cannot be retrieved automatically, only that retrieval is either over- or under-selective. If over-selective, it excludes the many noncanonical instantiations of the phrase; if under-selective, manual intervention is essential to discard irrelevant examples.

It is in seeking to extract phrases from computer corpus data that the difference between phrases and lexical bundles becomes clear. *Lexical bundles* (Biber, Johansson, Leech, Conrad, & Finegan, 1999) are uninterrupted strings of three or more words which recur with significant frequency in a data set. Since they are defined in terms of statistical frequency, they can also be identified and retrieved statistically: any three-word sequence in a data set can be said to be a lexical bundle provided that its frequency matches or exceeds the established cut-off point.

Phrases are on the whole much “messier” than lexical bundles, and automatic identification is only possible for completely frozen phrases and for the canonical forms of fixed and semi-fixed phrases. In other words, only phrases which are also lexical bundles can be retrieved automatically. Unfortunately, a great many phrases have a tendency to be variable. Noncanonical forms, as well as instantiations of semi-prepackaged phrases and idiom schemas, lack the regularity of lexical bundles, so much so that instantiations of phrases are often unique. As a consequence, they cannot be located automatically on the basis of recurrence or absolute frequency. The vast majority of lexical bundles, on the other hand, while identifiable automatically, are missing the “semantic completeness” that is necessary if they are to qualify as phrases. To give an example, the lexical bundle *a matter of* is a part of many established phrases (e.g., *it's a matter of life and death, it's only a matter of time, as a matter of fact*), but it must combine with other words before it can be said to express a complete meaning. It can be defined as a phrasal fragment, but it is not a proper phrase, while *as a matter of fact* is both a (frozen) phrase and a lexical bundle.

Since the majority of phrases are semi-fixed rather than completely frozen, there is a risk that they will not be picked up by algorithms designed to extract lexical bundles (or *n-grams*). These algorithms search for uninterrupted (“contiguous”) sequences of particular word forms, not interrupted sequences of lemmas. But where traditional *n-gram* location fails, more sophisticated search procedures come in. Recent advances have led to the development of skip-grams and concgrams, both of which are designed to overcome the

limitations of n-grams while remaining fully automatic (no human intervention required) and therefore empirically sound.

As the name suggests, a *skip-gram* (Guthrie, Allison, Liu, Guthrie, & Wilks, 2006) allows for interruptions to occur within the word string because the algorithm can ignore ("skip") up to four extraneous words. As a result, the recurrent words are located even if they do not always occur in an uninterrupted sequence. For example, it would allow the string *bear in mind* to be identified even when it occurs as *bear something in mind*, that is, with the direct object pronoun in its grammatically appropriate place, without classing *bear it in mind* or *bear what you said in mind* as distinct n-grams. The main limitation of skip-grams is that they are unable to process strings longer than three words in length (tri-grams), and the four-word skips, while apparently generous, may be insufficient even to allow for a modified noun in direct object position.

Concgrams (Cheng, Greaves, & Warren, 2006; Greaves & Warren, 2007; Greaves 2009) offer better coverage in both of these areas. Concgrams can process 2- 3- 4- and 5-grams, and the maximum skip between words is 50 characters, which is approximately 12 words (Greaves, 2009, p. 2). The n-grams can be extracted automatically (though this takes a very long time), or can be user-defined instead; for example, stipulating *bear* and *mind* to uncover all co-occurrences of those words, contiguous and noncontiguous. Additionally, the algorithm searches for the words in the n-gram irrespective of their sequential order. This makes it possible to extract a range of permutations which can be found in natural language, especially fronting (e.g., **in mind I'll bear it*) or reversal (e.g., *a wolf in sheep's clothing, every silver lining has a cloud*). These advances have greatly facilitated the extraction of phrases from corpora, but some problems remain. The most important of these is probably that inflected forms, being distinct character strings, belong to separate n-grams (a search for *bear in mind* will not retrieve *borne in mind*). There is also the perennial issue of meaningfulness: Algorithms calculate frequency and recurrence but cannot differentiate between a string that is meaningful and one that is not. As a result, the data retrieved using skip-grams or concgrams require manual intervention to discard irrelevant hits before analysis can take place.

Semi-Automatic Methods of Identifying and Extracting Phrases

The study of phrases has a long history in the pre-corpus era, and many phraseologists limit their study to decontextualized canonical forms. Corpus phraseology is largely a branch of corpus lexicography, and the most prevalent reason for studying phrases in corpus data is to examine how they are actually used in text, to improve descriptions for dictionaries and language learners. In order to do this effectively, it is essential to go beyond the canonical form alone and examine all the uses of a phrase in the data.

Before the appearance of concgrams, corpus phraseologists had no option but to make judicious and sometimes inventive use of the available query software. Locating phrases in all their permutations is not straightforward, because corpus query software is designed to locate character strings (words), not meanings. Different scholars have tackled the matter in different ways, but in essence all of them have resorted to multiple searches which are then collated and verified manually. The searches performed make use of well-established software tools which are included as a matter of routine in corpus query packages, namely the wild-card character and the intervening span. The wild card can be attached to the end of a word to represent any further characters, and therefore to retrieve inflectional variants of regular verbs, noun derivations, and so forth; it can also be used in place of any single word. The intervening span option allows skips to be inserted, typically up to a maximum of five words. Additionally, most commercially-available corpora have been lemmatized. Lemmatizing software indexes all inflected forms under their lemma, so if the data set has been lemmatized, it is possible to extract all inflected forms

in a single search. Applied to *bear in mind*, this would draw together *bear* and all its inflected forms: *bears*, *bearing*, *bore*, and *borne*. The advantage of a lemmatizer over a simple wild card is that it includes irregular forms alongside the regular ones: In other words, *bore* and *borne* are located with the help of a lemmatizer but not with a wild card (it would only retrieve *bear*, *bears*, and *bearing*).

Philip (2008, 2011) explains in some detail the kind of procedure that has to be followed in order to extract phrases semi-automatically from corpus data. The procedure is admittedly laborious, but at present the most exhaustive available. A first search extracts the canonical form. Subsequent searches are designed to extract inflectional variants, truncated forms (by shortening the string), inversion (by reversing the string), and substitution (using wild cards to replace actual words). In all of these searches, the number of possible intervening words is set at the maximum permitted by the query software (typically five). The combined queries are then collated and duplicates eliminated. Following this comes manual selection of the examples, in which instances of the phrase, including apparent exploitations and permutations, are set to one side and non-candidates discarded. Finally, the relevant concordances are subjected to analysis, which may be computer-aided if the selection is saved as a new file and run through a concordance package.

Working With Phrases

Extracting phrases from corpora is a means to an end, not the end itself. Only once the instantiations of a phrase—be it frozen or variable, in its canonical form or a variant—have been gathered together is it possible to proceed with linguistic analysis.

Phrases are meaningful by definition, but meaningfulness comes in several guises. In addition to the more familiar semantic meaning, phrases are also associated with pragmatic, functional meanings. Corpus phraseology views phrases as lexical items which, like single words, are part of “units of meaning” (Sinclair, 1996), meaning that they attract collocations, colligations, semantic preferences, and semantic prosodies in “concentric rings of phraseology” (Philip, 2011, p. 38). The semantic prosody of a phrase is its function, so it should come as no surprise that phrases can perform any one of a range of functions: They can be evaluative, situational, modalizing, text-organizational, or all of these (Moon, 1992, p. 495) in addition to, or indeed instead of, conveying information. Some phrases (e.g., *on the other hand*, *as it were*) are primarily pragmatic and have minimal semantic value; others—famously idioms—combine semantics with a range of expressive functions. These functions can be ascertained only by studying phrases in context. Corpus linguistic tools, automatic and semi-automatic, have allowed phraseology to move beyond semantics and syntax toward a fuller understanding of what phrases are used for, and why.

Technology and Learning Vocabulary

THOMAS COBB

To date, vocabulary is the dimension of language that has been most intimately involved with technology. Vocabulary is the subject of more entries in this section of the Encyclopedia than phonology, syntax, or pragmatics, and it has been subject to several distinct types of computational analysis—lexicographical, terminological, collocational, keyword, frequency, and others. But in terms of vocabulary learning, a simpler and older technology than any of these has had and continues to have the greatest effect on the kind and number of words that people can learn, and that is the technology of writing (Ong, 1982). When the practice of writing words down becomes widespread in a language, it determines the vocabulary that will have to be learned as well as offering the means for learning it.

That said, much of the vocabulary that anyone knows has been learned without any involvement of a technology at all. Infants hear speech streams, gradually infer their global meanings from context, and more gradually still, identify their units, including words. But lexicons acquired exclusively in this manner without the assistance of writing are destined to remain rudimentary, whether on the level of individuals or communities. Writing, as a recoding of the speech stream that slows its rate and enables repetition, review, and parsing, promotes far more extensive learning than real-time language use alone.

But as with many technologies, writing comes with a downside. The effect of making lexicons easier to learn by writing them down has been to make the overall task of vocabulary learning more difficult, because writing allows lexicons to expand up to and beyond the point of learnability. This entry looks at how writing and its allied technologies first made lexicons easier to learn, then harder to learn, but are now making them easy again.

The Vocabulary to Be Learned

When a language is spoken but not written, as was the case with all languages until relatively recently, and remains the case with most (Coulmas, 1989), there is a limit on how large its lexicon can become, one presumably imposed by the human memory and lifespan. If users of unwritten languages are required to encode progressively more complex messages, they tend to carve further distinctions within words (declensions, case endings, and verb categories) rather than coining new words, probably because it is easier to learn variations on known items than new items. Without a written form to suggest what the words in the speech stream actually are—the pieces of language between empty spaces—it is not clear the speech stream is ever very clearly parsed. Several unwritten languages “do not have a word for *word*” (Coulmas, 1989, p. 20). Research with language users that have for some reason missed out on acquiring literacy suggests that they may not have a word for *word* either. Tarone studied the language use of young Somali immigrants to the United States who had never learned a written language, and found they lacked very basic word handling skills such as repeating pseudowords and building associations between phonologically similar units (Tarone, Bigelow, & Hansen, 2007). Such inabilities can be predicted to limit vocabulary learning from oral input.

Vocabulary size counts of preliterate languages are necessarily inferential, but it seems that about 10,000 lemmas (headwords plus inflections and tenses) is the norm. This is the calculated size of several unwritten Australian languages (Dixon, 1980, p. 2). Even in the 12th century, five centuries after Old English was given a written form by Christian missionaries, it comprised only 20,000 lemmas (based on a count of the University of Toronto's *Dictionary of Old English Corpus*, ca. 2005). English now comprises some 470,000 headwords (in *Webster's Third New International Dictionary, Unabridged*, with the 1993 Addenda). English is always a special case, with its many incoming and outgoing linguistic invasions, but the pattern obtains: there is no major written language with a lexicon as small as 10,000 words. Of course, no current speaker of English knows anything like its entire lexicon. Goulden, Nation, and Read (1990) calculated that even educated adult native speakers have recognition knowledge of only 13,000 to 17,000 word families, so it is reasonable to infer that less educated or semiliterate adults would have knowledge of fewer words than that, or something roughly comparable to the size of an unwritten language.

When words are written down in a consistent form with spaces on either side, some of the burden of identifying and remembering them is offloaded to an external memory, and hence more words can be tracked and accessed. There are two versions of the argument for the cognitive consequences of writing. Members of the "Toronto school" conclude that the invention and use of phonetic writing caused new kinds of thinking to become possible (the position of Goody, Olson, Havelock Ellis, and McLuhan). Other students of writing effects find in writing mainly the possibilities of supporting, offloading, and extending memory (e.g., Donald, 1991), without any necessity of causality. The argument here is adequately framed by the latter proposal. Words written down are also more difficult for the language to prune through collective forgetting or dark ages; written lexicons tend to pile up relentlessly. Of course, not all ways of writing words down lift the memory burdens of vocabulary learning equally. Writing systems are constituted to favor one of two constituencies, those learning a language or its experienced users (Sampson, 1985; Venezky, 2004). Spanish with its abundant and reliable phonological information and small number of perceptual units (letters and letter parts) favors the learner; words known in speech can easily be identified in writing, and vice versa. Chinese with its minimal phonological information and vast number of perceptual units favors rapid processing by those who manage to learn it. A logographic or Hanzi text can be read about three times faster than the same text written in romanized Pinyin by readers who are equally experienced in both scripts (according to Sun & Feng, 1999).

Very large lexicons generally, in whatever writing system, also favor competent users at the expense of learners. There are simply a lot of words to learn in a language like English or French. Academic underachievement is a topic of growing concern in educational policy and research in most Western countries, and increasingly researchers are identifying lexical inadequacy as a major cause. Cummins (1981) observed that children often master the vocabulary of interpersonal communication but fail to develop the "cognitive and academic" language proficiency that is encoded in less familiar lexis. Corson (1985) went further, postulating a "lexical bar" consisting of the terms of science, analysis, and research which many children never become familiar with. Chall and Jacobs (2003) identified a widespread "fourth grade slump" at about age 10 when schoolchildren move beyond the lexis of familiar situations toward that of written texts.

The problem of inadequate lexis is particularly acute for those who wish to function at a high level in a second language (L2), as a large and growing number presently wish to do, especially in English. Perhaps this explains why it was mainly researchers concerned with English as an L2 who tackled the too-much-vocabulary problem with a view to finding solutions. A number of L2 pedagogical theorists had long experimented with ways of making the vocabulary learning task more manageable for learners of English (Palmer,

1917; West, 1926/1955), but this goal awaited the development of text computing to become truly attainable.

The computational analysis of text is a natural development of the basic technology of writing, a secondary literacy, in terms of what it reveals to language users about the language they are using. Writing systems exposed basic patterns in language, such as where words start and stop, and to this text analysis adds how many and which words there are in a text, in which other texts they also occur, and how frequently or infrequently. It also refines definitions of where words really start and stop, that is, not necessarily at the spaces, for example, in the case of multiword units like “by and large” or “as a matter of fact.” But the effects of these two literacies are potentially quite different. If primary literacy expanded the lexicon out of the reach of many L1 and most L2 learners, the secondary literacy can be used to bring it back.

There may be a half million words in English, but how many of them are needed to function in a particular context? Corpus linguists since the 1970s have built progressively more comprehensive models of languages as machine-readable text corpora (Kučera & Francis, 1967; Leech, Rayson, & Wilson, 2001). Pedagogical scholars have found ways to use these corpora to calculate the effect of knowing different amounts of vocabulary for different purposes (Nation, 2006; Cobb, 2007). Text coverage has now been calculated for several different functional domains including conversation (Adolphs & Schmitt, 2003), academic reading (Coxhead, 2000), domain specific reading (Chung & Nation, 2004), and the discourse of TV and movies (Webb & Rodgers, 2009). Coverage data twinned with comprehension data (e.g., by Schmitt, Jiang, & Grabe, 2011) shows reasonably clearly that the 6,000 to 8,000 most frequent word families are needed for reading in an academic environment, a challenging yet learnable figure. This research is in progress, with several important refinements under way, including Martinez and Schmitt’s calculation (described in Martinez & Murphy, 2011) of the coverage of the most frequent multiword units, and Cobb’s (in press) calculation of the coverage of the separate words buried in high-frequency homographs like “bank.” Basic versions of this technology are available for teachers now, such as the Vocabprofile Web site (<http://lex tutor.ca/vp/bnc/>) which helps teachers modify learning input to a particular frequency zone. Some experts in the field are currently experimenting with Web searches for texts at particular lexical levels. The goal is to help learners focus on the words they need rather than casting them adrift on the open seas of lexis.

From this perspective, then, while one language technology (writing) allowed lexicons to expand to or beyond the limits of learnability, another (text analysis) is busy discovering zones of learnability within these lexicons. But even when clearly identified, such zones will still number word families in the hundreds or even thousands and mastering them will remain a daunting task inevitably left largely to individuals to accomplish. What resources will be available to individuals wishing to undertake a substantial vocabulary upgrade?

The Means of Learning Vocabulary

Learning to read is clearly the first and biggest step in building a lexicon, but is reading alone, even in a targeted lexical zone, the most efficient method of vocabulary expansion? This is one of the most vexed questions in applied linguistics research. A conclusion reached by many researchers (e.g., Laufer, 2005; Cobb, 2008) is that while reading is typically an adequate resource for L1 lexicon building (but see Chall & Jacobs, 2003), it typically is not for L2 lexicon building (but see McQuillan & Krashen, 2008). This section looks at vocabulary learning technologies that go beyond simply meeting words in reading.

Writing is no longer the only technology that can slow language down and render it plain for retention and learning purposes. Numerous types of spoken language media can now perform some version of one or more of these functions, including cassettes, MP3 sound files, and DVDs. Some media can do this in conjunction with writing, whether prerecorded audio-texts, videos with subtitling, or real-time text-to-speech created by computer programs. While there is as yet no true text-to-image technology, vast databanks of images both still and moving have been constructed matching much of the high-frequency lexicons of several languages (e.g., by Rosetta Stone, www.rosettastone.com/).

And yet the most interesting approaches to accelerated vocabulary acquisition continue to proceed from written representations with any additional media playing a supplementary role. What the more recent learning technologies add to the basic technology of writing is decontextualized simulations of word handling tasks. These tasks are basically four in number—retrieving forms from meanings, meanings from forms, holding forms in memory, and adapting meanings to novel contexts. A set of word cards remains the basic paradigm for achieving the first three of these.

The data structure of a word card—more likely nowadays to appear on a computer screen or game console than on the two sides of an actual card—divides the word's information into two parts, front and back, shown and hidden, with roles reversible. One part is the to-be-learned word or phrase, the other some information associated with the word, whether a short definition in L1 or L2, a picture, a translation, a context sentence with the word missing, or other pertinent associate. The learner shuffles the word cards (or clicks randomize), looks at the cards one at a time, tries to recall the information on the other side, confirms his or her response and undertakes remedial learning as needed, and so on through pack or stack, then repeats. The "other side" can of course be either side. In one round the learner looks at the word and tries to recall the meaning, and in the next looks at the meaning and tries to produce the word. These receptive and productive activities are two of the basic word handling operations mentioned above, and the third—retaining the form in memory—is involved in both of them. An array of strong paired-associate studies from the verbal learning era of psychology (up to roughly 1970) underpins the use of word learning cards, many of them brought to bear on vocabulary expansion in an interesting paper by Mondria and Mondria-De Vries (1994). These researchers propose a plan for recycling the word cards in a shoe box of five compartments: all words start in the first compartment and move toward the fifth and thence out of the system if their information is consistently recalled, or back toward the front if not. Words that need the practice get it, and vice versa, and numerous words can pass through the system efficiently.

Word cards are also supported by research findings more recent than those of the paired-associate studies. The emphasis on form in word cards, for example, exploits the findings of Barcroft (2006) that the learning of form not meaning is in some ways the greater challenge of word learning. The emphasis on speed and repetitive practice exploits Segalowitz and Hulstijn's (2005) finding that lexical access is key to language processing. Word cards have also proven a useful laboratory for exploring second language learning variables, for example Elgort's (2007) finding that the gloss on the card back is more useful for advanced learners in the target language than in the L1.

Numerous versions of word cards and flashcards now appear on both Internet and mobile devices bringing with them such computational advantages as algorithms for sequencing the presentation, record keeping, and the capacity to make and store large numbers of cards easily. In the case of electronic flash cards, card-back information can include multiple choice items instead of simple translations or glosses, or other word associations and representations in the form of images, sound files, video clips, and whatever other information might be linked from the World Wide Web (iKnow! at <http://smart.fm/> allows learners

to import Flickr images from www.flickr.com). Reviews and comparisons of word card learning systems including the following are provided by Godwin-Jones (2010) and Nakata (2011): SuperMemo (www.supermemo.com/), vTrain (www.vtrain.net/), MemoryLifter (www.memorylifter.com/), P-Study (www.takke.jp/), WordChamp (www.wordchamp.com/), Quizlet (www.quizlet.com/), eSpindle (www.learnthat.org/), and Word Engine (www.wordengine.jp/).

However, as Nakata notes, few if any of these card systems offer opportunities for generative use of learned items (meeting or using words in new contexts, the fourth basic handling operation mentioned above). And few if any access information from a corpus or dictionary. A system attempting to do some of these is Horst, Cobb, and Nicolae's (2005) Group Lex (http://www.lexutor.ca/group_lex/demo_lab/), where learners enter their own words and definitions, hear their words rendered in text-to-speech, build and take quizzes using their own or each other's contexts (Which word goes in this context? Which word corresponds to this gloss?), and then novel contexts from a level-appropriate corpus.

Not one of these learning systems reviewed by Nakata appears to (a) focus on timed interactions and automaticity development, (b) tell learners which words they should be looking at beyond those they have found for themselves, or (c) facilitate game interactions or other opportunities for collaborative learning, a key idea in both the socioconstructivist and social networking agendas. One system attempting to do all three is My Word Coach for Nintendo (<http://mywordcoach.us.ubi.com/>). The tutor inside this set of interactive real-time games knows in advance the entire lexicon of English—or at least the 14,500 most frequent words of the British National Corpus frequency list (Leech et al., 2001)—knows the learner, uses a high quality learner dictionary for its glosses (*Cambridge Advanced Learner's Dictionary*), encourages wireless collaboration and timed competition between learners, and has undergone extensive testing with strong results on several dimensions of word knowledge (Cobb, 2011).

Beyond Word Cards

The use of word cards is of course not the only vocabulary learning technology imaginable. Indeed, no amount of beefing up of the paired-associate model can move it very far from the beginner end of the word learning process. Word card systems, pairing words with small glosses or translations, or practicing the recognition of form, are closer to the initial phase of word acquisition than the final, that being the complex, generative fitting of known words to novel contexts as required for the productive skills of speech and writing or even the receptive skills of high level reading and real-time speech processing.

Two kinds of technology support for the refinement of existing vocabulary knowledge are available to both L2 and L1 learners. The first is simply the vast array of learning opportunities present in the communications technologies currently available. A learner can receive input in almost any L2 of almost any quantity and quality from any location through devices with options that serve language-learning purposes whether or not intended to do so. Media players can be paused and repeated. Radio broadcasts that were interrupted or poorly comprehended can be retrieved as podcasts and listened to again. Hemingway's strategy of learning French by reading the daily news first in English and then in French was only possible because he lived in Paris; but now with newspapers in every major and most minor languages online, any learner can adopt this practice for any pair of languages for the price of an Internet connection. Language learners without their own corpora and concordance programs can Google for their collocates in a writing assignment (Is it "approaches to a solution" or "approaches for"?). The opportunities for vocabulary enrichment in integrated gaming environments like Second Life have barely been contemplated.

But there are some more limited, deliberate technologies for deepening existing vocabulary knowledge. A number of these at various degrees of trialing and testing are under development on Cobb's Lextutor Web site to support the more advanced learner's vocabulary development in contexts of actual language use. This stage of vocabulary learning may be better named "lexicogrammatical learning" since grammar becomes more relevant as a feature of word use as learning proceeds. Some examples follow.

Reading: Lextutor's hypertext builders link users' texts to a set of click-on resources including text-to-speech for individual words or short phrases, recorded speech or video where available for whole texts, dictionary, or concordances for any word or expression, and a simple means of storing words of interest for post-reading investigation (<http://lextutor.ca/hypertext/>), research, and related development program (Cobb, 2009).

Writing: Writers in search of the next word or its form for the texts they are writing can click to get a concordance for the last word they managed to get down (or last two, or last three) to see if there are any patterns in the Brown corpus that are applicable to their choice (http://lextutor.ca/concord_writer/).

Error feedback: Teachers embed links to selected corpus information beside their learners' collocation or other errors in electronic submissions. Learners correct the error in light of the corpus information. Described and tested in Gaskell and Cobb (2004; http://lextutor.ca/concordancers/concord_e.html).

Metalinguistic awareness: Learners submit their own texts to Vocabprofile analysis (<http://lextutor.ca/vp/>) or Keyword analysis (<http://lextutor.ca/keywords/>) to reflect on how the lexical properties of their own texts compare to those of other learners or native speakers.

Reaction time: Learners send their own word selections to a pedagogically adapted lexical decision task instrument as a means to build up their word recognition speed and work toward automaticity (<http://lextutor.ca/rt/>).

Future

It is argued here that spoken language does not normally create stable word representations, and hence, that learning vocabulary from spoken language alone takes place slowly and not very extensively. But this picture could change in the near future with the emergence of automatic speech recognition (ASR) technology. If any spoken utterance such as a phone conversation could be simply transformed into an accurate written rendition with a device that was, say, a part of one's mobile telephone, then the vocabulary learning opportunities of speech would be significantly expanded and the distinction between speech and writing significantly reduced. Such a realignment could make a big difference to vocabulary learning, since most people listen to far more language than they read. We are perhaps 10 years away from a highly usable version of such a technology.

Conclusion

If the sizes of modern written lexicons are prodigious, the tools available for coming to grips with them are also prodigious. This entry proposes that language technologies and lexicons grow together—as more words can be learned, more words will need to be learned, in a dynamic growth scenario that shows no sign of abating. But it also proposes what was created by technology can also be managed by it.

Few would dispute that vocabulary is the aspect of language learning that has been most involved with information technology up to now, but they might not agree about

the reason. The reason commonly given is that discreet units like words are all that the current state of information technology can handle. A more interesting reason is that technologies and lexicons were intimates long before the advent of computer technology and they form a natural pair.

Technology and Teaching Writing

JOEL BLOCH

Writing teachers aim to prepare their students to meet future writing demands both in and outside of academia. These demands are inextricably linked to the technologies that students will use to perform a wider and wider range of both digital- and print-based writing tasks. Since the introduction of the personal computer, technology has been shown to be a valuable tool in the teaching of writing. Walter Ong (1982) pointed out that all forms of writing are also types of technologies. Pencils, pens, and typewriters are technologies as are computers, computer networks, and the various writing spaces, such as Web pages, blogs, social networking sites, and Twitter, that today are found on the World Wide Web. In this sense, the technologies used for writing can be seen as an expanding set of resources, each with inherent strengths and weaknesses for particular functions. Tim Berners-Lee (1999), one of the first developers of the World Wide Web, has written that these new technologies, which today are sometimes known as Web 2.0 technologies or collectively as the "Read/Write Web," have been primarily designed to make it easier to create and publish information. The writing teacher's challenge is to understand the strengths and limitations of these technologies well enough to make the best use of them. In this entry, I examine how these new technologies have affected the teaching of writing. This entry is divided into four parts: a short history of the use of technology, new opportunities for using technology for teaching writing, the challenges for using technology, and suggestions for overcoming them.

A Short History of the Use of Technology in the Writing Classroom

The history of literacy has demonstrated that the definition of being literate is constantly evolving. Literacy has always been affected when new technologies are introduced. The invention of the printing press has been said to have led to the Protestant revolution by increasing the availability of the Bible (Eisenstein, 1979). This evolution has affected both the importance given to the various forms of literacy and the pedagogical approaches used to teach them (Graff, 1987). The growth of the Internet as both a writing tool and a writing space has greatly accelerated this change by supporting new forms of written communication, each different from the others. Since the introduction of the computer into the language-learning classroom in the early 1980s, technology has been a valuable tool for teaching writing despite the initial fears about how technology could replace the teacher. In reality, technology has turned out to be supportive of traditional and new approaches for teaching writing. For example, multiple drafting, which was a cornerstone of the various process approaches to writing, was facilitated by the ease with which one can use word-processing programs to revise or edit a paper without having to retype it each time. Early uses of technology included helping students with the invention of ideas, another important aspect of the process approach. The evolution of the pedagogical importance of the social aspects of the writing process was likewise facilitated by the development of computer networks, first with local networks that linked students and teachers within a classroom and then with ever wider networks that connected users worldwide (Bloch, 2007). The development

2 TECHNOLOGY AND TEACHING WRITING

of asynchronous discourse, such as e-mail, listservs, forums, and blogs that are read in a different time frame from that in which they are written, and synchronous discourse, such as chat and virtual worlds that are read in the same time frame, has provided the means to write in a variety of ways to a variety of audiences using a variety of different forms of language (e.g., Warschauer, 1999). This development was accentuated with the introduction of multimedia, computer games, and social networking sites, all of which can provide different spaces and motivations for writing. Publishing this writing and participating in the development of new information on the Internet have further changed the nature of social interactions between the writer and the reader, as well as the nature of the writer's audience. Both asynchronous and synchronous forms can be used for generating and sharing ideas in a social context throughout the writing process for teacher-student and student-student interactions, each of which can produce varying forms of literacy, student motivations for learning and using technology, and connections between the reader and the writer. Other forms of reader-writer interaction, such as teacher commenting or peer review, have also evolved with the development of the traditional word-processing technologies. The comment function found in most word-processing programs, for example, allows both teachers and students to place their own comments in a text; the writer can respond to each comment the reader has made. These technologies have produced varying forms of literacy, often depending on their internal nature or architecture, and how they have been implemented. For example, the production of synchronous and asynchronous discourses can involve different cognitive processes and social interactions, each of which can produce various forms of discourse. Chat is produced spontaneously without much advanced planning, much like group discussions or face-to-face tutorials. Listservs or blogs, on the other hand, can promote more in-depth discussions that can be shared at any time throughout the writing process. When using these forms of online discourse, teachers must clearly choose which technology better matches their goals for the class.

New Opportunities for Teaching Writing

These technologies have provided students the ability to publish their writing to audiences far beyond that of their teacher and their classroom. These changes have affected how we read, write, access information, and interact with each other, leading to what Bolter (2001) called a new paradigm in reading and writing by changing how texts are created, distributed, and read. The ongoing development of the World Wide Web has supported new technologies that can be used not only as tools for writing but also as new forms of literacy. Web pages, cell phones, and Twitter are being used to create novels as well as short communications that can be used for discussions. The evolution of the World Wide Web has also created new opportunities for publishing and accessing information that can transcend the boundaries of the classroom and the limitations of print text. Students can publish their writing, enhanced with pictures, images, audio, video, and layout design, to whoever can access the Internet, thus providing a different audience and writing experience. Digital storytelling, for example, is a form of multimedia literacy that encourages writers to synthesize their written texts with images, audio, and video to explore different ways that these modalities can create new forms of inquiry and meaning, thus exploring new ways of writing and thinking (Lambert, 2010). Twitter, for example, has also been used for back-channeling lectures and discussions, which can have positive as well as negative implications for teaching. Political reporting and even protests are being organized around the world using cell phones, Twitter, blogs, YouTube, and a host of other networked technologies (Rheingold, 2003). Cloud computing, where applications are located on the Internet rather than on individual computers, has changed how users can collaborate with

each other and share information. These new writing spaces have raised challenging possibilities for students who have different strengths and weaknesses in their literacy development, as well as for students who may need to use these new forms of literacy for communicating throughout their careers and personal lives (Bloch, 2008). Each technology raises its own questions about literacy, authorship, and identity, and therefore each can play a different role in developing student literacy. Bolter (2001) argued, for example, that Web pages can decentralize the relationship between the reader and the writer by giving readers more control over leaving one page and connecting to another. As the worldwide use of Wikipedia shows, wikis can promote the idea that texts are never finished and can be continually improved through collaboration. Although blogs can be individually or collectively authored, the popularity of individual bloggers writing in many different languages about every possible topic has reinvigorated the centrality of the online author (Bloch, 2007). As authored texts, blogs can support students in developing their own unique voices as well as providing texts that other students can incorporate into their writing. Grammar teaching has been changed dramatically by the introduction of Web-based concordancing programs that are freely available to teachers and students (e.g., Hunston, 2000). Programs such as the View (www.corpus.byu.edu/bnc) are freely available. These are also interesting examples of how the design and implementation of a technology can affect its use. Access to these programs can depend on the architecture of the technology; therefore changing this architecture can affect who can use them and how they are used. For example, the interface that connects users to the database can affect the availability of the program and the ease with which it can be used. While traditional concordancing programs were primarily used by researchers to study language, the ability to access these programs online has made them available to both teachers and students whenever the programs are needed to create teaching materials and to solve syntactic and lexical problems. Programs can also be integrated with other technologies to create new types of learning environments. The URL of a concordancing program can be inserted into a written comment in the text on a student paper, so that the student can directly access the program to help respond to the teacher's suggestions, whenever and wherever that information is needed. The way teachers and students access and share information has been greatly enhanced by new online Web sites that support the ability to tag and aggregate information. Users can collect, filter, and share information from the Internet for either personal or group use. Older technologies, such as listservs, e-mail, and chat, remain popular with writing teachers for helping students develop and share their ideas as well as to communicate with other users worldwide. Newer technologies, such as cell phone apps, may someday become important teaching tools. Each new form of technological literacy raises both old and new questions about what it means to be a literate person and what are the consequences of these new forms of literacy for the development of the students' more traditional writing skills.

Challenges in Using Technology for Teaching Writing

These new developments can also be overwhelming for teachers. Bombarded continually by the introduction of newer technologies, often not specifically designed for teaching writing but with great potential, teachers often feel compelled to implement new technologies even before understanding the old ones. Researchers may not be able to keep up with this onslaught either. Some technologies, such as virtual worlds like Second Life, have steeper learning curves and technical requirements, which can reduce the number of teachers and researchers who can use these technologies and consequently the number of new ideas for developing new uses. The backgrounds of the students can also become

a critical factor in how technologies are used. Teachers today often encounter a generation of “digital natives” who not only may know more about the technology than the teachers do, but may also bring different values, attitudes, and experiences to writing and technology than did previous generations of students, although how different these students are is not always clear (Palfrey & Gasser, 2008). As a result, teachers may cede some control over the classroom to better-trained students, and students may better develop their learning autonomy. Each technology has its own limitations as well. For example, a teacher wishing to use the comment functions found on most blogging services and word-processing programs to allow for discussion between the reader and the writer may discover that this feature may not promote the kinds of interaction that chat or e-mail can (Bloch, 2007). Blogs can also be useful for publishing and sharing ideas, but, despite their commenting functions, may not be as useful for collaborating. Wikis, on the other hand, can be used both for publishing texts as well as for promoting collaboration and peer review. Tweets, which are limited to 140 characters, can create opportunities for writing and social interaction but may not allow for the deeper development of ideas or the incorporation of multimedia. Social media sites, such as YouTube or Facebook, may be useful for publishing and sharing information but also raise new concerns about its privacy and control. The architecture or structure of the technology can also affect its implementation. The use of some technologies may require a large investment of time for training students. For example, the ease with which concordancing programs could be accessed did not mean that teachers and especially students who were not familiar with them could use them easily. Additional training, along with the possible redesign of the user interface, is necessary for new users to become familiar with these programs. With the growing importance of digital forms of multimedia to add new modalities to the traditional print forms of literacy, teachers who have focused only on print literacy may have to become visually literate as well. Old problems can become intensified online. The ease with which information can be cut and pasted from the Internet has led teachers to fear a “plagiarism epidemic” (Howard, 2007), which has sometimes turned the Internet into a technological battlefield between students cutting and pasting materials and teachers employing plagiarism detection Web sites to catch them. For both teachers and students, the great abundance of information on the Internet has also raised a number of complex issues about the legal and moral use of intellectual property for educational purposes in a global society. Both teachers and students must become more aware of their rights to use intellectual property and the legal and ethical constraints on its usage if they want to be effective citizens of the World Wide Web.

Overcoming Challenges

I would like to suggest three guiding principles for teachers to consider for implementing and evaluating technology in the writing classroom. The first is that technology is never neutral. Each implementation of an individual technology or a group of technologies can affect the outcomes in the classroom (e.g., Feenberg, 2002). Such outcomes can vary depending on the implementation individually or in combination with other technologies, the backgrounds and attitudes of both the teachers and students, and the nature of the writing tasks. The second principle is that the introduction of technology is never deterministic. The impact of factors such as teacher or student background can be modified by additional training, the design of the technology, classroom integration, and the quality of outside technical support. Even minor changes in the implementation, such as the training or support given to students, can affect the outcomes of technological use. Some problems can be mitigated by substituting one technology for another or combining different

technologies; for example, integrating the URL of a concordancing Web site into a word-processing file. One important consequence of these two principles is that it is difficult to generalize the failures and success of a technology in one context to other contexts. The third, and perhaps most important, principle is that teachers should decide which technologies to use by first analyzing the kinds of problems they wish to solve and the backgrounds of their students, and not by the technologies they might want to use. The proliferation of new technologies has forced teachers to consider even more carefully the relationship between the literacy goals of their courses and the specific literacies produced using each technology. Then teachers must decide how to modify their implementation to respond to the kinds of problems that will inevitably occur.

Conclusion

The growing importance of technology as a tool and as a form of literacy has been a worldwide phenomenon. Being able to access the Internet has long been an important concern for teachers. Today, access does not simply refer to being able to log on to the Internet but includes having a wide variety of unrestricted information available at a price one can afford. These technologies have given both teachers and students more autonomy in how they learn and with whom they learn. The so-called “digital natives” may not be intimidated by these new technologies but still may not know how to use them effectively. The growing complexity of the new technologies has increased the need for teacher training and professional development, while the availability of 24/7 access to other teachers and often open access materials and research has helped meet this challenge. Teachers can set up their own personal learning spaces where this information can be aggregated so that these materials can be used individually or shared with others. Web sites such as Netvibes, and tagging programs such as Diigo, which allow users to place information in categories of their own choosing, can help teachers and students conduct research, collaborate, and create new texts. The introduction of every form of technology and the resulting development of every form of literacy have always prompted similar questions, an issue Plato raised two thousand years ago when he questioned the effect of literacy on memory. What kinds of cognitive skills are involved with each form of literacy? How does the introduction of new technologies change social relationships? Do some forms of literacy produce more complex texts that affect how the information is read and understood? How do these concepts of authorship and audience affect the writing process? What has been learned from the long history of thinking about the use of technology is that answering these questions becomes more complex as new technologies and the resulting new forms of digital literacy emerge. As Graff (1987) warns, becoming literate does not always bring the benefits that are promised, either to the teacher or to the learner. The one overriding question that many teachers have asked from the moment technology was first introduced into the language classroom is “Do these technologies make for better language learners?” This question has always been difficult to answer, in part because of the complexity of factors that make it difficult to generalize from one context to another. To grasp these issues, teachers must cross disciplinary boundaries to better understand the complexities of using technology (Bloch, 2007). These include CALL research (e.g., Hanson-Smith & Rilling, 2007) and first language composition teaching as well as research in the theory and pedagogy of technology (Selfe, 1999; Feenberg, 2002) and intellectual property law (e.g., Lessing, 1999, 2008). The continuing growth of the Internet will inevitably challenge and frustrate teachers as more and more new technologies come online, which will continue changing the nature of literacy and how it is taught. However, these new technologies can provide teachers the opportunities to connect with each other as well as with new sources

of information to better meet these frustrations and exploit their pedagogical potential for the development of 21st-century literacies. As Selfe (1999) argues, teachers must pay attention to technology in both its micro-usage, to further the educational goals of the classroom, and its macro-usage, to further the social and economic goals of their society.

Technology and Usage-Based Teaching Applications

DEE GARDNER

Recent advances in computer technology have allowed the study of human language to progress in ways that were not possible when experts relied on human judgments alone (Sinclair, 2004). One of the chief developments in this regard has been the compilation and exploration of substantial collections of electronic texts consisting of language in its actual use. These “usage-based” language collections—referred to as *corpora* (singular, *corpus*)—exist in many languages of the world (German, French, Chinese, Spanish, Portuguese, etc.), with English corpora being by far the most extensively developed and investigated to date, and therefore the primary focus of the remaining discussion.

During the past 15 to 20 years, this technological boon for language study has led to the creation of large *mega-corpora*, many of which have been systematically organized according to genre (conversation, scripted speeches, newspaper and magazine articles, fiction, academic prose, etc.). The most influential of these large “structured” corpora are:

1. British National Corpus (BNC); 100 million words; publicly accessible; www.natcorp.ox.ac.uk/
2. Corpus of Contemporary American English (COCA); 400 million words and growing; publicly accessible; www.americancorpus.org/
3. Bank of English, also known as the Collins Corpus; 2.5 billion words and growing; publicly accessible; <http://web.quick.cz/jaedth/Introduction%20to%20CCS.htm>
4. Cambridge International Corpus (CIC); 1 billion words and growing; privately held; http://www.cambridge.org/elt/corpus/international_corpus2.htm
5. Oxford English Corpus; 2 billion words; privately held; www.askoxford.com/oec/?view=uk
6. Longman Spoken and Written English Corpus (LSWE); 40 million words; privately held.

Linguistic discoveries involving these structured mega-corpora are now well-documented, and include extensive descriptions of grammar, word frequencies, multiword items (idioms, phrasal verbs, etc.), and collocates (the common neighbors of words). Many of these corpus investigations have also resulted in the publication of extensive reference resources for language training such as descriptive grammars and dictionaries for language learners.

Several corpora of more specialized language have also been created and extensively investigated, such as the Michigan Corpus of Academic Spoken English or MICASE (Simpson, Briggs, Ovens, & Swales, 2002) and the International Corpus of Learner English or ICLE (Granger, 2003). Additionally, there has been a growing interest in the extremely large unstructured language corpora available on the Web through search engines such as Google, with access to words and word combinations possibly numbering in the trillions. These are also beginning to make their way into language education and user-friendly online corpus applications for the Web are beginning to emerge.

Indeed, electronic corpora have recently inspired a host of usage-based or “data-driven” teaching resources and methods, which are based on the way people really talk or write,

rather than on the intuitions of researchers, course designers, materials developers, or even instructors themselves. While corpus-based sources of data for language training have been around for nearly 80 years, thanks to tedious manual calculations and rudimentary computer analyses in the early days of linguistic computing, the recent rise of the modern machine-searchable mega-corpora, the growing number of more specialized electronic corpora, and the general availability of high-powered personal computers have spawned a new generation of technology-driven, usage-based teaching applications that are reshaping not only what is being taught, but how it is being taught. To date, the areas that have been most affected deal primarily with vocabulary, grammar, and discourse issues, although more top-level aspects of language such as pragmatics and metaphor are beginning to be impacted as well. The remainder of this discussion will focus on three areas of language education that to date have received the most attention in the pertinent literature: lexical and lexicogrammatical teaching approaches, corpus-based technology applications for language teaching and learning, and teacher training involving usage-based language applications.

Lexical and Lexicogrammatical Teaching Approaches

Usage-based teaching applications have had a significant impact in emphasizing the role of vocabulary (lexis) and the intricate connections between vocabulary and grammar (lexicogrammar). The pioneering work in the 1980s with the Bank of English led to the first major corpus-based teaching application in the form of a *lexical syllabus* (Sinclair & Renouf, 1988), which was further developed into *The Lexical Syllabus: A New Approach to Language Teaching* (Willis, 1990).

However, the most publicized of the vocabulary-centered teaching curricula has been *The Lexical Approach* (Lewis, 1993). Relying heavily on corpus-based analyses of real language, this approach puts vocabulary squarely in the middle of the instructional emphasis, paying particular attention to the broader notion of lexis, which includes not only single words, but also collocations (groups of words that tend to co-occur) such as common expressions (e.g., *how are you, good morning*), phrasal verbs (e.g., *break up, put out*), idioms (e.g., *kick the bucket, pop the question*), other frequently occurring word combinations (e.g., *economic forecast, absurd idea, chemical reaction*), and *colligations*—a more general type of collocation where certain words or types of words regularly co-occur with or within particular grammatical patterns (*I think that . . . , I hope that . . . , etc.*, but not *I ran that . . . , I swim that . . . , etc.*).

According to Lewis (2000), evidence from modern electronic corpora suggests that “millions” of these various types of collocations exist in the English language, leading him to conclude that “Within the mental lexicon, collocation is the most powerful force in the creation and comprehension of all naturally occurring text” (pp. 48–9). Language teaching under this concept emphasizes the identification, production, and combination of frequently occurring groups of words (chunks) to meet learners’ real communication needs, claiming to mirror the way that most native speakers naturally store and use the language to save mental processing energy during actual communication. It is based on the principle of frequencies of word-patterns in actual usage (*grammaticalized lexis*), and represents a radical shift from traditional grammar-based teaching approaches, which often emphasize the construction of novel sentences based on known grammatical rules and structures (*lexicalized grammar*).

A somewhat more balanced view of the roles of lexis and grammar in language education is found in the *pattern grammar* approach (Hunston, Francis, & Manning, 1997). Again based on frequencies in actual usage from a mega-corpus, this view suggest that the English

language is comprised of patterns of words that have both lexical and grammatical significance, and that groups of words with similar patterns tend to share similar meanings. For instance, Hunston et al. (1997) suggest that words meaning “shout” or “make a noise” such as *bark*, *growl*, *hiss*, and *yell* are mostly found in the grammatical pattern Verb + *at* + Noun (e.g., *bark at the cat*, *growl at the man*, *hiss at the dog*, *yell at the umpire*). Advocates of pattern grammar summarize the instructional goals for their approach as follows:

Patterns can form an integral part of a structural or notional syllabus, but their association with lexis make[s] them a natural accompaniment to a lexical approach. They can be seen as putting the grammatical “flesh” on to the “bones” of a lexical syllabus. (Hunston et al., 1997, p. 215)

A more recent application of usage-based data is Cambridge’s *Touchstone* series (McCarthy, 2004). Drawing from the North American English portion of the Cambridge International Corpus, the designers claim to have identified “the most useful grammar and vocabulary for learners from a basic to an intermediate level,” and “how people communicate in everyday situations, especially in conversation” (p. 2). The designers then utilize this information as the basis for the language instructional approach found in the *Touchstone* series.

Finally, no discussion of corpus-based vocabulary applications would be complete without mention of the vocabulary-levels approach of Nation and his colleagues (Nation, 2001), which has had perhaps the greatest impact on the general fields of applied linguistics and TESOL (teaching English to speakers of other languages). In brief, this approach emphasizes the distribution of vocabulary in written and spoken texts in terms of corpus-based, pre-determined lists of words (general high-frequency words and academic high-frequency words) and words not on those lists (technical, topic-specific, and low frequency words).

Especially pertinent to our current topic is the fact that Nation and his colleagues have developed (a) user-friendly computer programs such as Range, which can identify and categorize the vocabulary of essentially any text or combination of texts (up to 32 texts) to meet specific instructional contexts and needs, and (b) usage-based vocabulary assessment tools such as the Vocabulary Size Test, which can be used for language proficiency testing and instructional placement purposes (both programs are currently downloadable at <http://www.victoria.ac.nz/lals/staff/paul-nation.aspx>). While this vocabulary-levels approach (and its associated technologies) does not constitute a vocabulary curriculum itself, its supporting role continues to impact large numbers of language training curricula, including Nation’s own recent work on curriculum design in language education. Cobb (*n.d.*) has recently adapted these vocabulary tools for use on the Web (www.lex tutor.ca/), and has coupled them with his own online applications to assist language teachers and learners with various vocabulary issues.

Corpus-Based Technology Applications for Language Teaching and Learning

Bernardini (2004) makes the distinction between “uses of corpora as sources of descriptive insights relevant to language teaching/learning and uses of corpora that directly affect the learning and teaching process(es)” (p. 15). While the lines between these two uses of corpora may be blurred at times in the literature, it might be helpful to think of the distinction as “resources” versus “methods.” However, for purposes of our present discussion, we rely on both types to provide a more general description of the way technology and corpora have combined to shape many aspects of language education in recent years.

Concordancing

The most frequent connection between electronic corpora and classroom language instruction has been in the practice of concordancing, which is essentially computer-generated lines of text from actual corpora with a key word or words in context (KWIC) highlighted in each line, as seen in the following selected and reformatted lines for the key word “chip” retrieved from the search engine used with the Corpus of Contemporary American English (COCA) (Davies, 2008):

1	2009	MAG	America	Christian becomes material in the hands of the sculptor, who will lop off and <i>chip</i> away as he sees fit. This is one reason for the strong reactions for
31	2009	MAG	GolfMag	If your shot flies too far, you'll leave yourself plenty of room to <i>chip</i> the ball and run it up close. Pars are scarce when you're chipping
36	2009	MAG	GoodHouse	and spices. Our 20 volunteers didn't need any prodding to grab a tortilla <i>chip</i> and dig in—and you won't either with these primo picks. First
42	2009	MAG	PCWorld	scramble data as it's written to disk. Seagate's Maxtor BlackArmor puts the <i>chip</i> on the hard drive's circuitry, in what's called full-disk encryption.
56	2009	NEWS	NewYorkTimes	she said, only made her tougher.” If you've got a <i>chip</i> on your shoulder and you're dysfunctional, you'll either be depressed or repressed
61	2009	NEWS	SanFrancisco	mini grilled cheese sandwiches, French fries (of course) and warm chocolate <i>chip</i> cookies with iced milk shooters. # “They absorb the alcohol,” Ms.

Concordance lines can be used by teachers and more advanced learners to study such language issues as morphologically related words (e.g., *chip*, *chips*, *chipping*, *chipped*), close synonyms (*utter* silence, but not *sheer* silence; *sheer* beauty, but not *utter* beauty), grammatical parts of speech (nouns, verbs, adjective, adverbs, articles, etc.), collocations (compound nouns, fixed phrases, idioms, etc.), grammatical structures (progressive aspect, passive voice, etc.), and language varieties (US vs. UK English, spoken vs. written English, etc.).

Chief among the free, publicly accessible search engines are the various interfaces to the 100-million word British National Corpus (BNC), including:

1. Xaira-BNC (Oxford University Computing Services, *n.d.*, www.oucs.ox.ac.uk/rts/xaira/)
2. Phrases in English or PIE (Fletcher, 2003, <http://phrasesinenglish.org/>).
3. BYU-BNC: The British National Corpus (Davies, 2004, <http://corpus.byu.edu/bnc/>).

The search engine for the more than 400-million word Corpus of Contemporary American English or COCA (Davies, 2008, www.american Corpus.org) is perhaps the most versatile and widely available interface currently online, and is rapidly gaining in popularity, with approximately 50,000 unique users (based on Google Analytics) since it came online two

years ago (Mark Davies, personal communication, March 26, 2010). Making concordancing and other corpus consultations possible for the average language learner and teacher is the hallmark of the COCA search engine.

Historically, concordancing in language education has been used by actual learners to promote vocabulary development through repeated contextual exposures, and to enhance their awareness of the specific linguistic characteristics of various academic genres such as medical research articles, PhD theses, and various business-related writings. In fact, the use of corpus-based concordancing in English-for-specific-purposes education has been recognized for several years (reviewed in Flowerdew, 2005), and the explosion of literature in this area over the past 10 years confirms that it is a readily accepted methodology among many educational researchers and language educators, especially in the higher levels of academic training.

English for Specific Purposes

In our own review of recent usage-based teaching applications, we found an astounding number of articles covering a variety of corpus-driven applications in specialized language areas, such as biochemistry, history, biology, business English, tax accountant writing, research article introductions, medical studies, general academic prose, professional legal education, and even office hour consultations. These, and many others, were published within the past 10 years, attesting to the fact that usage-based or data-driven methodologies have found a home in contexts where specific academic English is being studied, and especially where learners are being asked to distinguish between different genres of the language.

Additionally, the rise of various *learner corpora* in such settings have allowed teachers and researchers the opportunity to study typical uses of a target language by nonnative writers and speakers and to compare these between various language groups and against native (target language) norms (Gilquin, Granger, & Paquot, 2007). In short, this rich source of data shows teachers and learners where target language growth is happening well and not happening well, and, therefore, where work is needed.

However, the clear connection between technologically heavy corpus applications and higher education is not as readily apparent in more elementary levels of language training. In fact, the inductive nature of learning from concordance lines—that is, learning language patterns, meanings, and rules from examples—is often viewed as a necessary skill to take advantage of concordancing and related methods. This is not a skill normally associated with lower proficiency language learners. Although attempts are being made to close this apparent gap between corpus-driven learning and instruction at lower levels of language competence, it nonetheless remains one of the greatest obstacles for full acceptance of corpus-based methodologies in language education.

Teacher Education and Usage-Based Language Applications

McCarthy (2008) points out that while language teachers have been known to be consumers of corpus-based materials, such as language-rich reference grammars and dictionaries, they have not been as quick to embrace corpus-based resources from the perspective of conducting their own research or as “reflective” practitioners (p. 564). He concludes that this is likely due to a lack of specific corpus-based training in their formal education as teachers.

In the most extensive review to date of teacher and learner attitudes toward data-driven learning (DDL), Boulton (2009) also cites teachers’ sheer lack of exposure to corpora and corpus applications as the main obstacle to full acceptance of these modern methods in

the language classroom. In short, “DDL has simply not yet penetrated the consciousness of the teaching profession world-wide” (p. 91). According to Boulton, insufficient teacher training with corpora often leads to unnecessary skepticism, because teachers struggle to figure out how to incorporate such methods into their primary language instruction; they may see some use for themselves, but are apprehensive to expose learners to corpus applications, and they often feel burdened by the time commitment required to adopt fully such methods, especially because they are generally treated as optional training and are rarely part of their normal course examinations.

Additionally, for technology-driven, usage-based teaching applications to meet the diverse needs of language professionals, teacher education must also begin to encourage and train teachers to develop and utilize their own classroom-specific corpora (McCarthy, 2008). This will require teachers in training to not only understand the concepts of basic corpus construction, but also become familiar with technological applications and tools for analyzing them, such as:

1. Compleat Lexical Tutor (www.lextutor.ca/)
2. Range and Frequency Programs (www.victoria.ac.nz/lals/staff/paul-nation.aspx)
3. WordSmith Tools (www.lexically.net/wordsmith/)
4. Xaira (www.oucs.ox.ac.uk/rts/xaira/)
5. MonoConc (<http://www.athel.com/mono.html>)
6. WordCruncher (www.hlanalysis.com/WordCruncher/WC.aspx)
7. AntConc and AntWordProfiler (<http://www.antlab.sci.waseda.ac.jp/software.html>)

Finally, technology in usage-based teaching applications falls under the much more general area of technologies in education, and should therefore be treated with the same rigor as any such innovations. Failure to do so could be costly in terms of human and monetary resources expended. On the other hand, with rigorous evaluation and appropriate adjustments, technology-driven, usage-based applications hold great promise for advancing the way languages are taught and learned.

Technology-Supported Materials for Language Teaching

DOROTHY M. CHUN

Introduction

In using technology to support language teaching, it is important to consider first what one's goals are and what research has shown with regard to instructed second language acquisition (SLA). If the goals are to meet the ACTFL (2006) Standards (the five Cs: communication, cultures, connections, comparisons, communities) or the CEF (Common European Framework) (Council of Europe, 2001), then communicative competence and the ability to understand and compare languages and cultures would be high priorities. Research in computer-assisted language learning (CALL) has flourished, both in terms of determining effective uses of technology and in advancing SLA theories (see Hubbard, 2009, which is a four-volume compilation of seminal work in CALL, and Chapelle, 2009, who discusses a number of theoretical SLA perspectives and how they have influenced the development of CALL materials and tasks). Chapelle (2009) proposes that the expanding use of technology changes the nature of communicative competence theory:

communicative competence needs to include the ability to communicate using readily accessible L2 technology aids (such as online bilingual dictionaries and tools that check grammar), the ability to make appropriate linguistic choices in face-to-face, remote, written, and oral modes, and the ability to choose appropriate technologies for communication and language learning. (p. 750)

This entry will provide a brief overview of the types of technology-supported materials that have been shown to be effective for language learning and a preview of the currently available technologies that have the potential to aid language teaching. To oversimplify (due to length constraints), CALL materials will be categorized chronologically, with reference to technological capabilities (pre-World Wide Web, Web 1.0, Web 2.0, and Web 3.0), and to the SLA theories prevalent at the time (see Table 1).

Table 1 Overview of CALL materials

	<i>Pre-World Wide Web</i>	<i>Web 1.0</i>	<i>Web 2.0</i>	<i>Web 3.0</i>
Types of CALL	Tutorial Multimedia software	Read-only Interactivity CMC	Read-Write Social networking communities	Portable personal Augmented reality
Main SLA theories	Behavioral, cognitive linguistic	Psycholinguistic, interactionist	Sociocultural Teaching language in use	Ecological, cultural-historical

Early CALL (Pre-World Wide Web)

Prior to the creation of the World Wide Web (www) in 1993, CALL materials were first developed in the 1970s and 1980s as stand-alone software programs for mainframe and personal computers and were primarily tutorial in nature, providing drill and practice for vocabulary, grammar, and the traditional four skills. Learners could do vocabulary and grammar drills and receive immediate feedback for discrete point answers. They could record themselves speaking, and, if they had access to acoustic phonetic software, they could see visualizations of their intonation curves.

Exercises for listening, reading, and writing could be done on computers, and computerized bilingual dictionaries were available. The use of multimedia (text, visuals, audio) in the 1990s was found to be effective as it provided learners with information about their L2 in multiple modes. For example, studies found that when learners receive both textual and pictorial information about lexical items, they learned these vocabulary words better than when they accessed textual or pictorial glosses alone (e.g., Chun & Plass, 1996a). Similarly, when learners both heard the way words were pronounced and saw visual representations of the words, they remembered these words better than when they only saw a visual (Jones & Plass, 2002). For L2 reading, the effect of using multimedia to improve comprehension has been mixed. Some studies have shown that multimedia glosses are effective for aiding comprehension (Yanguas, 2009) and that video previews can enhance comprehension (Chun & Plass, 1996b). Although Erçetin (2003) found that contextual video annotations are accessed significantly more than textual, audio, or picture annotations, other studies showed significant *negative* relationships between reading comprehension and graphic and video annotations (Plass, Chun, Mayer, & Leutner, 2003).

In line with the emphasis on communicative language teaching (CLT) in the 1980s and 1990s, early forms of computer-mediated communication (CMC), such as e-mail and local area networks, allowed L2 learners to communicate in their L2. Computer-assisted written classroom discussion, for example, allowed greater participation and provided learners with opportunities to express a wider range of discourse functions than in typical, spoken classroom discourse (Chun, 1994). In terms of cultural learning, in early CALL, videos and films could be viewed on videodiscs, and learners could perform related exercises in order to enhance their cultural knowledge.

Web 1.0

With the emergence of the World Wide Web in 1993, the first generation Web 1.0 was primarily “read-only” content on static Web sites, and the Internet provided greater (and instantaneous) access to authentic L2 texts and materials than had been available before. During this period, software and Web sites were developed to be more “interactive,” going beyond tutorial CALL. Language instructors and CALL developers capitalized on the possibilities for more immediate and expanded forms of CMC, allowing for communication in the L2 with native speakers. Asynchronous CMC, such as bulletin boards and forums, and synchronous CMC, such as instant messaging and text chatting, increased opportunities for L2 use. Studies found that the use of such tools enhanced language learning by simulating face-to-face conversation and that text chatting might have a positive effect on real-time L2 speaking (Payne & Ross, 2005). Asynchronous discussions were shown to be similar to the question–response–evaluation sequence of the traditional language class, while in synchronous discussions, the quantity and quality of discourse functions were found to be similar to those in face-to-face conversations (Sotillo, 2000).

CMC studies provided valuable insights into SLA processes. For example, synchronous chat was shown to provide many of the same benefits ascribed to the interaction hypothesis

and the negotiation of meaning (Blake, 2000; Lee, 2001). With the growing focus since the turn of the millennium on culture and intercultural communicative competence (ICC) and on the application of sociocultural theory to L2 learning, studies have revealed both advantages (Müller-Hartmann, 2000) and pitfalls (O'Dowd & Ritter, 2006) of using CMC.

Web 2.0

Web 2.0 (a term mentioned as early as 1999 by DiNucci but closely associated with the O'Reilly Media Web 2.0 conference in 2004) might be characterized as a "read-write," user-generated content, sharing, collaborative tool, including such technologies as blogs, wikis, social networking sites, and picture and video sharing sites. For L2 learners, blogs and wikis allow them to become active authors and work collaboratively online through social networks, increasing their authentic language use and their intercultural communicative competence (Ducate & Lomicka, 2008).

In line with contemporary approaches to L2 learning, both first (Web 1.0) and second (Web 2.0) generation CMC tools have shown positive results, allowing learners to negotiate for meaning, develop their identities and increase intercultural understanding. Enhancing agency and authorship have also been suggested as primary benefits of using Web 2.0 tools for communication (Warschauer & Grimes, 2007).

Emerging studies have reported on other types of the second generation of CMC tools, for example, podcasting, videoconferencing, social networking sites in languages other than English, microblogging on Twitter, collaborative writing in wikis, chatbots as peer or tool for language learners, the virtual world *Second Life*, and multiuser virtual environments for L2 language and pragmatics acquisition. In addition to virtual social spaces, massively multiplayer online gaming spaces (MMOG) are also being investigated for their potential for L2 learning (Sykes, Oskoz, & Thorne, 2008). These studies all contribute to Chapelle's (2009) vision that the goal of expanded communicative competence should include L2 learners' ability to communicate in multiple modes (face-to-face, remote, written, and oral).

Web 3.0 and the Future of CALL

The third generation Web 3.0 has been labeled the "portable personal web," and for L2 learners, this will allow even greater personalization of language learning tools, complementing the subfield of intelligent CALL (ICALL), which has the capacity for a deeper analysis of learner input and individualization of the learning process (Heift, 2010). Mobile devices will become increasingly multifaceted, though the question remains as to whether mobile platforms will be as effective as computers (Stockwell, 2010). In addition, the accessibility of mobile devices at all times may well result in the blurring of the distinction between school and nonschool learning, that is, learning inside versus outside the classroom. Also to be studied for their effect on L2 learning will be Web 3.0 technologies for "augmented reality," which can provide live direct (or indirect) views of a real-world L2 environment whose elements are augmented by virtual computer-generated imagery.

Contemplating the future of technology for language learning is an exciting prospect. It is this author's opinion that the greatest promise is in hybrid or blended learning environments, in which technology is seamlessly integrated into everyday teaching, learning, and communicating. As Chapelle (2009) cautioned, language teachers will need to choose appropriate technologies based on what has been shown to be effective. In developing multiliteracies in the 21st century, it is becoming clear that learning will take place in and beyond the L2 classroom.

Tense and Aspect

KATHLEEN BARDOVI-HARLIG

The term “tense and aspect” actually includes three terms, *tense*, *grammatical aspect*, and *lexical aspect*. It is rather likely that readers of this volume may have encountered these concepts in nonspecialist and pedagogical literature conflated under the term *tense*. These terms refer to three distinct but related concepts. *Tense* locates an event or situation on the time line. In English, *John loves Mary* (present) and *John loved Mary* (past) show a difference in tense. *Grammatical aspect* provides a means of expressing one’s view of a situation or event. For example, we may view an event as completed or continuing. *John sang* (simple past) and *John was singing* (past progressive) show a contrast in grammatical aspect, although both are in the past tense. Both *tense* and *grammatical aspect* refer to categories of verbal morphology. In contrast, *lexical aspect* deals with the semantics of a predicate. For example, a predicate may express a state or an action (compare *John seems happy* and *John swims*), or an action with duration or one that has no duration (*John changed the tire* and *John recognized Mary*).

Tense

Tense is a deictic category that locates an event on the time line, usually with reference to the time of speaking (Comrie, 1976; Dahl, 1985). When we encounter the term *tense* we typically think of past, present, and future. Reichenbach (1947) developed a notational system along the time line which is still referenced today. The three components of the Reichenbach analysis are E (event time), R (reference time), and S (speech time). In the past, for example, event time and reference time co-occur and precede speech time (E, R > S); in the present, the three coincide (S, R, E). The pluperfect, sometimes called the past-in-the-past (*When I got there, the class had begun*), is considered a relative-absolute tense, whereas the present and past are absolute tenses. As in all past tenses, the event (“the class began”) takes place before the time of speaking (E > S), but the pluperfect refers to another event (i.e., “getting there”), represented as E > R > S. The most common interpretation of the present perfect is current relevance of a past situation (Comrie, 1976). Following Reichenbach, this is expressed as E > R, S.

Although future is often thought of as a tense, not all languages have a morphological future. Spanish, French, and Italian, for example, have morphological futures, but English does not. Instead, English uses the modal *will* to indicate future. Many languages also have a *go*-future in which the verbs *go* or *come* form a periphrastic future (Bybee, Perkins, & Pagliuca, 1994). The future is always semantically modal because the future is always partially imagined; intention, volition, and desire are part of the semantics of future expression (Bybee, 1985; Dahl, 1985).

Although tense locates events on the time line, it is important to note that languages also employ other linguistic means to redundantly or exclusively place events in time; these include the use of adverbials, calendric references, and even place names to order events. All languages have lexical means of referring to time, but not all languages mark tense.

Grammatical Aspect

In contrast to tense, *grammatical aspect* does not locate an event or situation on the time line, nor does it relate the time of one situation to another. Rather, it is concerned with “the internal temporal constituency of one situation; one could state the difference as one between situation-internal time ([grammatical] aspect) and situation-external time (tense)” (Comrie, 1976, p. 5). Grammatical aspects provide different ways of viewing situations (Comrie, 1976; Smith, 1983; Dahl, 1985). In Romance languages there are two past tense forms—the perfective and the imperfective. The perfective forms—*pretérito* in Spanish, *passé composé* in French, and *passato prossimo* in Italian—encode the view of a situation or event as a whole and as completed. In contrast, the imperfective past—*imperfecto* in Spanish, *imparfait* in French, and *imperfetto* in Italian—encode explicit reference to the internal temporal structure of a situation, “viewing a situation from within” (Comrie, 1976, p. 24). Germanic languages generally lack the morphological distinction of preterite and imperfect found in the Romance languages. English exhibits contrast between the progressive and the simple, whereas neither German nor Dutch marks grammatical aspect as English does. According to Comrie, the characteristics of the imperfective in all languages tend to be habituality and continuousness/durativity.

An important consequence of viewpoint aspect (i.e., grammatical aspect) is that the same occurrences can be reported in different ways. For example, an event can be presented as one event in an ordered series in which case it is viewed as completed and carries the perfective past: *Chaplin came home . . . He picked an orange, kicked the orange outside, and they had dinner.* Alternatively the narrator might open up the event with the progressive: *They were having dinner, and Chaplin realized there was no milk* (adapted from a learner narrative [Bardovi-Harlig, 1998]). The event is still completed, but for the purpose of the narrative, it opens an interval during which another event occurred.

Lexical Aspect

Lexical aspect—which deals with the semantics of predicates and their inherent temporal make-up—has been divided in various ways. For example, readers may recall a division from language arts lessons that distinguishes between description verbs (such as *be*, *seem*, *have*) and action verbs which parallels the linguistic distinction between stative and dynamic predicates. This is a sound initial distinction, but binary aspectual distinctions tend to group dissimilar predicates together. One four-way analysis is traced back to Aristotle and was introduced to modern linguistics by the work of philosophers Vendler (1957/1967) and Kenny (1963). (See Binnick, 1991, for the history of the study of aspect.) Vendler proposed a four-way division that distinguishes the aspectual categories of states (STA), activities (ACT), accomplishments (ACC), and achievements (ACH). These are often referred to as Vendler categories.

Each of the categories has distinguishing characteristics. States persist over time without change. Examples of states include *seem*, *know*, *need*, *want*, and *be* (as in *be tall*, *big*, *green*). Activities have inherent duration and involve a span of time; like *sleep* and *snow* they have no specific endpoint. Examples of activities include *rain*, *play*, *walk*, and *talk*. Achievements capture the beginning or the end of an action (Mourelatos, 1981) as in *The race began* or *The game ended*, and can be thought of as reduced to a point (Andersen, 1991). Examples of achievements include *arrive*, *leave*, *notice*, *recognize*, and *fall asleep*. Accomplishments have both an endpoint (like achievements) and inherent duration (like activities). Examples of accomplishments include *build a house* and *paint a painting*. Achievements and accomplishments can be grouped together as telic predicates, known as “events” (Mourelatos, 1981).

The classes of statives and activities can be grouped together as atelic predicates. Aspectual categories apply to the verb and its arguments (Dowty, 1979; Freed, 1979) but are most commonly discussed as relating to predicates.

The Vendler categories can be distinguished by three features (Andersen, 1991): [$\pm$ punctual], [$\pm$ telic], and [$\pm$ dynamic]. The feature [+punctual] distinguishes achievements from all other verbs. The feature [+telic] distinguishes predicates with endpoints (*sing a song*) from those without (*sing*), and so distinguishes achievements and accomplishments from activities and statives. The feature [+dynamic] distinguishes dynamic predicates (for example, *play*, *read a book*, *wake up*) from stative predicates (such as *seem* and *know*).

The literature on lexical aspectual classes has developed diagnostic tests that distinguish the aspectual categories from each other. These tests are very important in applied linguistics, and for acquisition research discussed briefly below. One such test is the *in + time phrase/for + time phrase* test, which distinguishes activities from accomplishments and achievements. Activities are acceptable with adverbial phrases such as *for ten minutes*, but unacceptable with phrases such as *in ten minutes*. The fact that *John slept for an hour* is acceptable, but that ??*John slept in an hour* is not (indicated by question marks) indicates that *sleep* is an activity.

Accomplishments and achievements are acceptable with *in*-phrases, but unacceptable with *for*-phrases as seen with the accomplishment *build a house* which is acceptable in *John built a house in a year* but odd in ??*John built a house for a year* (the latter invites an interpretation in which the same house was built repeatedly for a year). The same results obtain for achievements such as *notice the painting*: *John noticed the painting in a few minutes*/?? *John noticed the painting for a few minutes* (Dowty, 1979).

The progressive test is often used to distinguish states from dynamic durative predicates (i.e., states and achievements from activities and accomplishments). States and achievements will fail the progressive test (**John is liking Mary*; **Susan is recognizing Bill*) whereas activities and accomplishments will pass (*Bob is swimming*; *Clarice is writing a book*). Dowty (1979) provides a comprehensive set of tests and reference lists of predicates by aspectual categories. (See Binnick, 1991, for a review).

Tests of the Vendler categories for languages other than English followed later and included Spanish, French, and Japanese (Jacobsen, 1982). Applied linguists have developed further tests for identifying lexical aspect in learner production. In addition, Shirai proposed ordering aspectual tests in both English and Japanese (Shirai, 1991, 1998) to improve efficiency and accuracy for coding natural production samples from both native speakers and learners (see Bardovi-Harlig, 2000, for a review).

Tense and aspect also play a role in narrative structure. Hopper observed that competent (native) users of a language “mark out a main route through the narrative and divert in some way those parts of the narrative that are not strictly relevant to this route” (Hopper, 1979, p. 239). The use of tense and aspect is one way that speakers distinguish the main events (the *foreground*) from the supporting events and information (the *background*). In the foreground successive events may be marked in the preterite or simple past. The foreground is on the narrative time line, but the background is not, and speakers may use the background to predict, interpret, or supply information about earlier or simultaneous events.

Tense and Aspect in Second Language Acquisition

Second language acquisition is one area of applied linguistics that has been actively investigated. The emergence of verbal morphology in second language acquisition has four main characteristics (Dietrich, Klein, & Noyau, 1995). First, the development of temporal

expression is slow and gradual. However succinctly analysts (or teachers) can describe a tense-aspect system of a language, learners acquire its formal components and form-meaning associations in stages that take time to complete. Second, as part of the slow and gradual acquisition of the tense-aspect system, form often precedes function and verbal morphology may emerge without the target meaning. Third, irregular morphology precedes regular morphology. Finally, learners tend initially to avoid discontinuous marking such as aux + V-tense inflection and formulate an initial hypothesis that tense is realized by suffixed inflections. This is reflected in the initial use of the past participle for the French *passé composé* and the Italian *passato prossimo* and of V-ing in English for the progressive.

L1 acquisition studies found that children were sensitive to lexical aspect in the morphological encoding of past events. Antinucci and Miller (1976) reported that in conversation seven Italian-speaking children and one English speaking child (ages 1;6 to 2;5) used the past participle with change of state verbs with clear results (e.g., *venire* 'come', *cascare* 'fall', *arrivare* 'arrive') but no past marker with states (e.g., *volere* 'want', *sapere* 'know') or activities (e.g., *volare* 'fly', *caminare* 'walk'). Bronckart and Sinclair (1973) reported similar results from an experimental production task in which 74 French-speaking children (ages 2;11 to 8;7) used perfective past forms (*passé composé*) for actions with clear results and present forms (*présent*) for inherently durative events. Bronckart and Sinclair (1973) and Antinucci and Miller (1976) concluded that young children encode events with past (tense) only when there is an endpoint; in other words, initial distribution of past morphology is determined not by time as in a tense system, but by lexical aspect.

With the L1 research as a background, second language acquisition researchers also began a similar line of investigation resulting in what has come to be known as the aspect hypothesis (Andersen, 1991). The aspect hypothesis maintains the importance of the initial influence of lexical aspect in the emergence and spread of tense-aspect morphology in past-time contexts. The aspect hypothesis can be broken down into four separate claims (Shirai, 1991, pp. 9–10; Andersen & Shirai, 1996), stated in terms of grammatical aspect and its relation to lexical aspect (following Vendler categories):

1. Learners first use (perfective) past marking on achievements and accomplishments, eventually extending use to activities and statives.
2. In languages that encode the perfective/imperfective distinction, imperfective past appears later than perfective past, and imperfect past marking begins with statives, extending next to activities, then to accomplishments, and finally to achievements.
3. In languages that have progressive aspect, progressive marking begins with activities, then extends to accomplishments and achievements.
4. Progressive markings are not incorrectly overextended to statives.

The acquisitional claim goes beyond the affinity of verbal morphology for predicates of semantically compatible lexical aspectual categories; it additionally claims that in the initial stages—in the past—verbal morphology will be in complementary distribution according to aspectual category, unlike in the target languages investigated in the same studies, where contrast is possible.

Recall that verbal morphology also plays a role in narrative structure. Learner narratives also follow linguistic universals: the *interlanguage discourse hypothesis* predicts that learners use emerging verbal morphology to distinguish foreground from background in narratives. Learners show greater use of perfective past in foreground than in the background. Moreover, they show greater use of imperfective and progressive in the background than in the foreground. Unlike the perfective past which can occur in both foreground and background, the imperfective and progressive only occur in the background in targetlike use (Bardovi-Harlig, 2000).

Using both frameworks, data from learners of English suggest a hierarchy that predicts which verbs in a narrative will be inflected by learners with limited linguistic resources:

1. Achievements are most likely to be inflected for simple past, regardless of grounding.
2. Accomplishments are the next most likely to exhibit the simple past. Foreground accomplishments show higher rates of use than background accomplishments.
3. Activities are the least likely of all the dynamic predicates to carry simple past, but foreground activities show higher rates of simple past inflection than background activities. Activities also show use of progressive in the background.

This illustrates the influence of lexical aspect and narrative structure in tense-aspect acquisition, and suggests areas for consideration by other areas of applied linguistics such as instruction and materials development.

Technology and Terminology

LYNNE BOWKER AND DES FISHER

Terminology is the discipline concerned with the collection, processing, description, and presentation of terms, which are lexical items used to designate concepts belonging to a specialized subject field (Sager, 1990, p. 2). Terminology and technology have a long history: one of the first applications of computers to language was the development of large-scale collections of terminology known as term banks. First developed in the 1960s, and still in use today, term banks contain a series of records, which present information about terms and the concepts they represent (e.g., grammatical category, definition, contexts, synonyms, foreign-language equivalents). They are essentially organized repositories of condensed terminological data.

The advantages of using an electronic storage medium are clear: space is not at a premium as is the case with printed resources, updates can be implemented more quickly, and contents can be searched and accessed more easily. However, while computers have long been used to store terminological data, the collection and analysis of information was done in a manual fashion—by gathering and poring over printed documents—for many, many years after the introduction of computers. Although any aspect of terminology work can be performed manually, such an approach is time-consuming and labor-intensive, which necessarily limits the amount of information that can be processed. Additionally, some types of information, such as frequency data, can be collected more reliably with computer assistance. Therefore, in recent decades, there has been a noticeable shift from the passive use of computers as mere repositories to the active integration of computerized tools into most areas of terminology work. Indeed, technological developments have permitted such improvements in productivity, quality, and accessibility that it has become virtually unthinkable for those carrying out terminological research not to take advantage of the wide range of electronic resources and tools available to them.

Terminology work has always been corpus-based in the sense that information about terms and concepts has been gathered primarily from texts. However, the increasing availability of documents in machine-readable form (e.g., Web, databases, e-books, and journals) means that terminologists can—with the help of specialized software—consult a wider range of documents than ever before. Electronic texts that meet project criteria (e.g., subject, date, language) can be gathered into a corpus and processed in a variety of ways using a range of tools (Bowker & Pearson, 2002).

Term Extractors

For example, one type of tool used by terminologists is a term extractor, which attempts to automatically identify all the potential terms in a corpus and then presents this list of candidates for verification. Term extractors can use any of several different underlying approaches (Cabr  Castellv , Estop  Bagot, & Vivaldi Palatresi, 2001; Lemay, L'Homme, & Drouin, 2005). Frequency- and recurrence-based techniques essentially look for repeated sequences of lexical items. The frequency threshold, which refers to the number of times that a sequence must be repeated, can often be specified by the user. Pattern-based techniques make use of part-of-speech-tagged corpora to search for predefined combinations

2 TECHNOLOGY AND TERMINOLOGY

of grammatical categories (e.g., adjective + noun) that typically correspond to term formation patterns. Meanwhile, corpus comparison techniques compare the relative frequency of a given lexical pattern in a small specialized corpus and a larger general reference corpus to determine the likelihood that the pattern corresponds to a term. Moreover, these various approaches can be combined in hybrid term-extraction systems.

Recent enhancements to some term extractors include the ability to handle lemmatization and orthographic variants. In addition, as illustrated in Figure 1, bilingual term-extraction systems attempt to identify the equivalents of candidate terms in parallel corpora (i.e., corpora of texts in one language aligned with their translation into another language), and currently, researchers are seeking ways to identify such equivalents in comparable (i.e., non-translated) corpora. While the lists of candidates generated by term extractors are not perfect—there will almost certainly be instances of both noise (non-pertinent items identified) and silence (relevant patterns missed)—they nonetheless provide a useful start for anyone having to identify terms in a large document or series of texts.

Corpus Analysis Tools

Once potential terms have been identified, terminologists can use these as access points into the corpus and go on to explore the surrounding context in more detail using tools such as concordancers. A concordancer searches for all occurrences of a specified pattern and displays the results in context in an easy-to-read format, such as a Key Word in Context (KWIC) display, as illustrated in Figure 2, or, in the case of a parallel corpus, in a bilingual display as shown in Figure 3. Note that concordancer searches can be simple (e.g., key word) or advanced (e.g., wildcard, Boolean, fuzzy).

Terminologists can read the surrounding context to learn more about the concept or the usage of the term. They can also sort the data according to words occurring before or after the search term to reveal phraseological patterns. Some corpus analysis tools can also calculate statistically significant collocations and co-occurrences (e.g., using mutual information, *t* scores, log likelihood). The value of including such information on term records is increasingly being recognized since many of the users of such resources (e.g., translators, technical writers) seek this type of usage information to help them with their task of producing a text that reads well.

In addition, corpora can be searched using knowledge patterns, which are lexical items that can reveal semantic relations between concepts (Meyer, 2001). For example, knowledge patterns such as *part of*, *consists of*, or *includes* might reveal a knowledge-rich context that illustrates a meronymic, or part-whole, relation between two concepts. This type of information can be helpful for learning more about concepts or for constructing useful definitions for inclusion on a term record.

Another useful type of information that can be obtained from corpora is frequency data. Computers excel at counting, and many corpus analysis tools include a feature that counts all the occurrences of each lexical item in a corpus. More advanced tools allow lemmatization and the disambiguation of homographs, which produces more accurate counts. Frequency data is difficult to gather manually, but it can be helpful for determining which of several variants or synonyms is more commonly used, for example. Similarly, information about frequency is used by terminometric tools, which aim to measure the degree of implantation of various concurrent terms designating the same concept in a subject field (Quirion & Lanthier, 2006).

Terminology Management Systems

While terminologists tend to compile the results of their research into vast and widely accessible lexical resources such as term banks, other language professionals also conduct terminological research. For example, individual translators often have to solve terminological problems they run into when translating a text. In order not to have to repeat this research in the future, many translators use a terminology management system (TMS) to create their own terminology databases or termbases, which can be likened to small-scale, personalized term banks.

When used as a stand-alone tool, a TMS is very similar to a term bank in that it is essentially a searchable repository for recording the results of terminological research. However, most translators use TMSs as part of an integrated tool suite or translation environment tool (TEnT), which may include a word processor, translation memory system, machine translation system, and term extractor. In this setting, a TMS takes on a much more active role, and this has had a considerable impact on how translators carry out their term research.

For instance, many TMSs have an active term recognition or automatic term look-up feature, which interacts directly with the word processor. The contents of the source text that the translator has to translate are automatically compared against those of the termbase. Whenever a match is identified, the translator is alerted that there is an entry for that term in the termbase. The translator can then consult the termbase entry and, if desired, paste the equivalent directly into the text with a single click. In fact, some TMSs go one step further and offer a feature known as pretranslation. If pretranslation is activated, the equivalents for all matches are automatically pasted into the text as part of a batch process. The advantages of using this type of integrated TMS are that translators can work more quickly and can ensure that terminology is used consistently.

Indeed, in order to further optimize their use of the technology, some translators have begun to change the way in which they record data on term records within a TMS. For instance, since the automated features such as active term recognition and pretranslation do not make use of information such as definitions or contexts, translators have begun to streamline the contents of their term records, often including only terms and their equivalents (O'Brien 1998, p. 118). In addition, as noted by Kenny (1999, p. 74), translators are no longer simply recording the canonical form of a term (e.g., infinitive form for verbs, masculine singular form for nouns) as advised by terminology textbooks (e.g., Sager 1990, p. 145). Instead, they are recording the most frequently encountered form, or even multiple forms, to facilitate one-click pasting into the target text without the need for additional editing.

Moreover, as observed by Bowker (2011), translators are not restricting themselves to including only terms on term records. Since any type of reusable information—term or otherwise—could prove useful, translators who work with TEnTs are beginning to fill their TMSs with records for a mixture of terms and nonterms, even though this contradicts the principles put forth in the terminology literature (e.g., Dubuc, 1997, p. 38). Such effects brought about by technology call into question how language professionals are trained in the use of terminology tools. Bowker and Marshman (2009), for example, have advocated a more integrated approach to technology training that better reflects the ways these tools are used in the contemporary workplace.

Prospects for Terminology and Technology

It is worth taking a brief look to the future to consider additional ways that technology might impact the terminology profession. For instance, work continues on the development

of standards for exchanging data between different terminology tools. Term Base eXchange (TBX) is an open, XML-based standard for exchanging structured terminological data; it has been approved as an international standard by the Localization Industry Standards Association (LISA) and will soon be published by the International Organization for Standardization (ISO). Furthermore, collaborative terminology ventures—particularly as part of volunteer efforts—are now facilitated through the use of wiki technology, which provides a centralized platform with a Web interface, templates, discussion pages, revision histories, and content protection options to allow for managed collaboration. Tools are also being developed to semi-automate the labor-intensive task of corpus construction (Barrière, 2006), as well as other aspects of corpus analysis (Barrière & Agbago, 2006).

Finally, in addition to being impacted by technology, it is worth noting that terminology research itself is contributing to the development of new tools. For example, terminology is playing a key role in the development of tools for ontology building or knowledge structuring, controlled-language checking, and information retrieval (including tasks such as query expansion and cross-language information retrieval). Thus, it is clear that terminology and technology will continue to evolve and influence one another in the years to come.

Terralingua

LUISA MAFFI

Terralingua (www.terralingua.org) is an international nongovernmental organization (NGO) founded in 1996. It is the world's first organization with a mission to sustain the biocultural diversity of life—our invaluable global heritage of biological, cultural, and linguistic diversity.

Terralingua's guiding idea is that the diversity of life is diversity in nature and culture, and that biodiversity, cultural diversity, and linguistic diversity are interrelated and interdependent. Historically, human communities co-evolved with the natural world in the process of adaptation for survival. In the course of this long-term adaptation, humans developed in-depth knowledge about their ecological niches and how to use and manage ecosystems and biodiversity in ways that ensured the continued availability of natural resources needed for survival. This cultural knowledge was encoded in the local languages and transmitted through language use. Therefore, there is an intimate, some would say inextricable, link between language, knowledge, and the environment.

The continued vitality of local languages and of the cultural knowledge they encode and transmit supports the continued vitality of the local ecosystems and their biodiversity. At the same time, thriving ecosystems and biodiversity sustain the people living in them and foster the thriving of their cultural knowledge and languages. Conversely, if there is a loss of vitality at any level, all other aspects of the diversity of life are affected. This inextricable link between language, knowledge, and the environment is what Terralingua refers to as "biocultural diversity" (Maffi, 2001; Harmon, 2002).

Most of the world's biocultural diversity is found in areas occupied by indigenous peoples. Indigenous languages make up 80–5% of the total number of living languages, which is estimated at 6,909 languages in the 2009 edition of *Ethnologue* (www.ethnologue.com), though most indigenous languages (with some notable exceptions) are spoken by relatively small populations. While there is no one-to-one correspondence between languages and cultures, languages can be taken as a useful proxy for cultural diversity, suggesting that most cultural diversity is also represented by indigenous peoples. Research conducted by Terralingua, mapping the global distribution of linguistic diversity against the global distribution of biodiversity (Oviedo, Maffi, & Larsen, 2000; Skutnabb-Kangas, Maffi, & Harmon, 2003; Stepp et al., 2004), has revealed significant overlaps between the geographic patterns of linguistic diversity and that of biodiversity worldwide, with most of the world's biodiversity located in areas of high linguistic diversity. The highest concentration of biocultural diversity occurs between the tropics, with three "core areas" in the Amazon Basin, Central Africa, and Indomalaysia-Melanesia (Harmon & Loh, 2004).

However, biocultural diversity is currently under serious threat. The world is experiencing a "converging crisis" of extinction of biological, cultural, and linguistic diversity. Global data on biodiversity loss show that between 1970 and 2005 there was a loss of 30% in the world's biodiversity. Terralingua's Index of Linguistic Diversity (Harmon & Loh, 2010) shows that, during the same period of time, global linguistic diversity has eroded at a similar pace: There has been a 20% decline since 1970. These mirroring trends suggest that biocultural diversity as a whole is on a downward path. An examination of the causes of this converging extinction crisis points to many of the same social, economic, political, and ecological factors affecting loss of diversity at all levels in a cumulative and synergistic

fashion. Therefore, it also follows that addressing the extinction crisis requires action at many levels.

For this reason, Terralingua advocates and applies an integrative approach to the conservation, maintenance, and revitalization of the diversity of life in all its forms, through a comprehensive program of research, education, policy-relevant work, and on-the-ground action. From a biocultural perspective, the conservation of biodiversity benefits from the maintenance and revitalization of local languages and cultures, and the maintenance and revitalization of languages and cultures is all the more effective insofar as it goes hand in hand with the conservation of the local biodiversity. Terralingua's book *Biocultural Diversity Conservation: A Global Sourcebook* (Maffi & Woodley, 2010) is the first analysis of integrative biocultural conservation efforts from all over the world. It illustrates a great diversity of initiatives taken by indigenous and local communities, and many organizations working with them, to sustain local languages, cultures, and environments.

These and the many other efforts that are taking place worldwide offer hope for stemming the global loss of biocultural diversity. However, to be sustained and to be fully successful, on-the-ground efforts need to be bolstered by policies favorable to biocultural diversity. Since 2000, there have been signs that an integrative biocultural perspective has begun to make its way into the statements of principle and the programs of work of major international organizations such as UNESCO, UNEP, IUCN, and several others. However, by and large actual policies for the integrated protection of linguistic, cultural, and biological diversity are still lagging behind the statements of principle. Furthermore, in principle binding protection of biocultural diversity can only be ensured through national legislation, and very few countries have taken any steps in this direction.

A major effort is needed to promote understanding of and appreciation for the biocultural diversity of life. Such an effort requires educating people about the vital importance of biocultural diversity for the future of humanity and all of life. In the second decade of its work, Terralingua is concentrating on this educational effort, through a variety of initiatives, building on earlier experiences such as its collaboration with UNESCO in the production of the educational booklet *Sharing a World of Difference: The Earth's Linguistic, Cultural, and Biological Diversity* (Skutnabb-Kangas et al., 2003). The goal is to create global awareness of and caring for biocultural diversity among students and the general public, so as to engender a groundswell of support for biocultural diversity and a favorable climate for the development of policy for biocultural diversity protection.

Test Design and Retrofit

GLENN FULCHER

Test Design

All defensible test design presupposes a clear and unambiguous statement of the test purpose. This involves documenting in a test framework the intended test-taking population, the uses for which this population is expected to use language, the inferences to be drawn from the test scores, and the precise nature of the decisions that will be made about individuals. Without a clear statement of purpose it is unclear what evidence might be relevant to a validation argument, or what principles might be used to make design decisions. As Rulon (1946, pp. 290–1) put it prophetically, “A test cannot be labeled as valid or not valid except for some purpose.”

This principle is universal and unequivocal, because tests are tools used by society and institutions to distribute limited resources to the most deserving on meritocratic grounds (Latham, 1877, pp. 28–9). The testing enterprise is one “in which the object is to select the most suitable persons for a certain purpose” (p. 2), and “The purpose of language testing is always to render information to aid in making intelligent decisions about possible courses of action” (Carroll, 1961, p. 314). This entails using test scores to make decisions about individuals that will impact upon their immediate and future prospects in life. It is therefore not ethically acceptable for high-stakes decisions to be made using instruments that are not demonstrably relevant, useful, and sufficient for the defined purpose.

There is therefore an intimate connection between the decisions to be made, the inferences about individuals drawn from scores, and test design. In order to explore this connection we find a useful analogy in architecture. Buildings are always designed with a purpose in mind. It would not occur to an architect to start work on the blueprints for a building without first defining its intended use. “No building, as far as I know, ever really delighted its users if it proved . . . unsuitable for their needs,” wrote Broadbent (1973, p. vii), arguing that building purpose and user needs should drive design, so that the building becomes “an environmental filter between man and his environment.” There is little point designing a hotel in which to house aircraft, or a cathedral as a family home. A language test is a filter between test takers and a postdecision future. There is no value in administering a test of academic English to migrant farm workers, or a business English test to oil-field engineers. Worst of all are buildings with no purpose at all, for they claim to be usable for any purpose. These are difficult to find, because architects realize their potential for dereliction. One such example is the London Dome, a structure meant to be endlessly adaptable, but which lay unused for seven years from the turn of the millennium until extensive (and extremely expensive) structural retrofits were undertaken to turn it into the O2 arena. The same is true of language testing. As Ingram (1968, p. 70) once refreshingly put it: “All tests are for a purpose. A test that is made up without a clear idea of what it is for, is no good.”

A link between test purpose, test design and validation has long been implicit in the assessment literature, even when validation was seen primarily as a post hoc activity. Working within primitive validity theory, researchers were keenly aware of the reverse chain of reasoning from decisions to design that we see in architecture. Ruch (1924, p. 13)

writes “For an examination to possess validity it is necessary that all the materials actually included be of prime importance, that the questions sample widely among the essentials over which complete mastery can reasonably be expected . . . and that proof can be brought forward that the test elements (questions) can be defended by arguments based on more than mere personal opinion.” The requirement for an argument to support the chain echoes down the decades (Kane, 2006), and is embedded in the primary standards of educational assessment (AERA, 1999, p. 17). In recent years the argument-based approach to validation has made the link between purpose, design, and validation much stronger. An interpretive argument that is constructed to justify a claim of score meaning minimally involves three inferences: a scoring inference that justifies the allocation of a score to an observable attribute, a generalization inference from the observation to the universe of generalization, and an extrapolation inference from the universe of generalization to the target domain (Kane, 2009, pp. 57–8). The observations, what test takers actually do under test conditions in relation to test tasks, must generate evidence that can be generalized well beyond the test itself. Thus, Mislevy (2007, p. 463) is correct when he states that “considerations of test use, even if implicit, are integral to design.” Fulcher and Davidson (2007, p. 51) take this one step further in arguing that all such considerations should be explicit, coining the phrase “effect-driven testing” to describe a model in which the role of the test designer is “to picture the effect the test is intended to have, and to structure the test development to achieve that effect” (p. 144). In common with architecture, this also implies that designers “think about intended beneficial impact as the test is built, and be willing to knock it down when things change” (p. 177).

The “nuts and bolts” of test design are therefore intimately and inevitably connected with test purpose and validation (Fulcher, 2010, p. 5). Evidence-centered design (ECD) (Mislevy, Almond, & Lukas, 2003) is a systematic approach to test and task design that links purpose to design through an evidential basis for design decisions (Pearlman, 2008), the outcome of which is embodied in test specifications. The evidence to support design decisions, the record of the design decisions, and the final design documents can then be compiled into a narrative that puts forward a case for supposing that inferences from test scores are useful and relevant for the intended test purpose. Chapelle (2008, p. 320) refers to this as a “validity argument from test design.” Examples of validity arguments such as those to support the use of the Internet-based Test of English as a Foreign Language (TOEFL iBT) show that design decisions, and the reasons for these decisions expressed as warrants and backings, now constitute the largest part of the argument (Chapelle, Enright, & Jamieson, 2010, p. 10).

Test design is therefore a form of architectural design activity, complete with an intended purpose and use, design documents, rationales, and criteria by which it is possible to judge the success of the outcome.

Test Retrofit

Once a test has been designed and is in operational use, it requires ongoing maintenance. By analogy with architecture, both buildings and tests require retrofits to incorporate state-of-the-art technologies and meet the changing needs of users. Buildings and tests that do not evolve will cease to be used and decay (Brand, 1994, p. 110). As Davies (2008, p. 110) says of the English Proficiency Test Battery (EPTB) and the English Language Testing Service (ELTS): “EPTB and ELTS were largely one-off operations, they were not maintained with new material on a regular basis and they did not have the advantage of being informed by new (and ongoing) research.” Both were ultimately demolished, and a new structure erected on the site.

“Retrofit” refers to the process of making changes to test specifications after the test has been rolled out for operational use. There are two primary motivations for retrofitting tests, which are parallel to those in architecture. The first is to make improvements to the test without altering its principal purpose; this is referred to as an “upgrade retrofit.” The second is to change or broaden the original purpose so that its use can be extended to additional groups of test takers; this is referred to as a “change retrofit” (Fulcher & Davidson, 2009).

Test Architecture

Test and architectural design are both modular, and involve design layers (Brand, 1994, pp. 12–23; Mislevy and Risconscente, 2005). Each layer in the design has its own unique function. While some layers may be modified independently, they all work together to create the intended effect. When a retrofit is proposed, it may affect one or many layers. The layers of design are illustrated in Figure 1.

The site of a building is the most stable and least likely to change. The structure is also difficult to alter, comprising as it does the foundations and the load-bearing components. However, retrofit is sometimes essential if the structure begins to weaken. The skin of the building is the exterior surface; this is replaced from time to time, either when new materials become available, fashions change radically, or the skin deteriorates so much that it is no longer water-resistant. The space plan is modified more frequently, depending on the number, and needs, of users. “Stuff” is moved around on a regular basis. Finally, the services include heating, plumbing, electrical wiring, ventilation, and so on. These are modified frequently in order to maintain the building in a useable condition as other layers are retrofitted. Each of the layers has a parallel in language testing, which can be partially explained using concepts from evidence-centered design.

Site	Models of communicative competence and language use change very little over time. Similarly, discourse practices in real-world domains, and the functions required to undertake specific purpose language tasks, are largely stable. These constitute the theoretical and descriptive building site, which only periodically experiences tectonic shifts.
Structure	The structure of a test is set out in a framework document that describes test purpose, the constructs of interest (from models), discourse domains relevant to the population of interest, task models, and other real-world criteria which score users wish to predict. Much applied linguistic work is

Figure 1 Layers of architectural design and retrofit © Glenn Fulcher

4 TEST DESIGN AND RETROFIT

required to create the structure, which is context-specific. For example, the genres and scripts of the service industry, and the constructs needed for successful performance, have changed little over time (Fulcher, Davidson, & Kemp, 2011).

The first two layers of site and structure are set out in a test framework document, while the layers below the structure are typically articulated in the test specifications.

Skin	The testing equivalent of the skin is the delivery model, which states how the test is delivered (e.g., Internet, computer, or paper and pencil), and the presentation model, which states what the test takers will encounter. Alterations to the skin are more frequent, but carried out only when essential because their high visibility often causes user unease in the face of impending change.
Space plan	The test assembly model creates the space plan for the test. This model states how long the test will take to administer, how long input material should be, and how many item types and of what kind should be included. The plan sets out how the domain is represented within the limited space available in a test.
Stuff	The individual items are the “stuff” that occupies the space. These are changed and moved around in test forms almost at will, although if new item types are introduced this would trigger a change to the services.
Services	The service layer provides a building with usability. In a test, the service layer is the interpretive argument (Kane, 2006) that provides the rationale for the decisions made in all other layers in order to justify the interpretations made from test scores, which in turn supports the use of the scores in decision making for the intended purpose. Thus, whenever a change is made in any architectural layer, the interpretive argument will need some adjustment.

Figure 2 Test architecture and retrofit (Fulcher & Davidson, 2009, p. 134)

A retrofit program may require changes to any or all of these levels. Figure 2 relates the levels of test design to the architectural layers. In the discussion of upgrade and change retrofits below, we suggest which layers are likely to be affected, although all retrofits are likely to minimally require changes to the services as the interpretive argument is the fundamental component that demonstrates that the test is fit for purpose.

Upgrade Retrofits

Upgrade retrofits are part of the process of building and test maintenance. They do not change test purpose but enhance it by improving its usability for intended functions. Upgrade retrofits almost always occur in the layers of the skin, space plan, or stuff, with appropriate alterations to services. In buildings, for example, accessibility for the disabled is a major impetus for retrofits to space plans. Similar accommodations are retrofitted for tests, primarily in the skin (e.g., Braille readers), or the space plan (e.g., timing) (Bolt & Thurlow, 2004).

Other upgrade retrofits to tests include the addition of new item types to better represent a construct, improving items to increase reliability (stuff), or adjusting subtest length (space plan) in order to achieve better content representativeness. Most reported retrofits operate within the lower architectural layers (Weir, 2003). For example, the most recent retrofit to the International English Language Testing System (IELTS) has been to the skin, with the launch of a computer-based version in 2005 (Davies, 2008, p. 102), and Davies indicates that future retrofits are likely to focus on improving the reliability of performance subtests (p. 110), which will be at the layer of space plan and stuff, with minor changes to services.

From time to time an upgrade retrofit requires alterations to the structure. In architecture, structural alterations are normally carried out when there is a threat to the safety of the building; seismic retrofit is the most common and is very expensive. For the same reason, structural retrofits are also rare in language testing and take place primarily when the existing structure can no longer support the required inferences and decisions. For example, in 1966 a listening subtest was added to the Cambridge Proficiency (CPE) test (Weir, 2003, p. 24), and in 2005–6 a speaking subtest was added to the Test of English as a Foreign Language (TOEFL) (Chapelle, Enright, & Jamieson, 2008). It is arguably the case that without these costly additions the tests may have become obsolete.

Tests, like buildings, are not “finished” when they start to be used. They must adapt if they are to keep pace with fashion, technology, and the ever changing demands of their users and occupiers.

Change Retrofits

Disraeli is reported to have said that “the secret of success is constancy of purpose.” Once the purpose is embedded in the structure of a building or a test, its future success depends upon constancy. As Davies (2008, p. 93) reports, when IELTS underwent a major usability review in 1993, “test purpose was to remain what it had been. . . .” As long as the structure remains in place, there is a clear rationale for the gradual evolution of other architectural layers.

Yet, there is tension between the principle of clear, unambiguous test purpose and the business objectives of many test providers. When there is a requirement to generate income from test sales, the most effective way of meeting targets is to increase test volume. Wendler and Powers (2009, p. 1) admit that “it is not difficult to see how an off-the-shelf product can bode well for an organization’s finances: New product development is slow and

expensive, and when businesses can attract new customers to their existing offerings, the result can have benefits—both for the organization's bottom line and, in terms of decreased costs, for customers also." This can involve using a test with a new population; drawing inferences that were not intended; and making decisions in completely new contexts.

This is the architectural equivalent of changing the use of the building from that which was originally intended. The church becomes a restaurant and bar, a substantial home is transformed into office accommodation, or a tower block into a motel. Change retrofits require extensive alteration at every architectural layer, including the services, which have to meet all the health and safety regulations appropriate to the new use. In testing, the primary validity standards must be addressed as if for the first time. In architecture, change retrofits are the subject of extensive consultation with all the people who are likely to be affected, and the relevant authorities who must be satisfied with the safety of the new use. While the same principles apply to language tests, they are not always applied.

With volume in mind, it has become customary for some test providers to list the variety of purposes for which a test is used by cataloging institutions or companies that "recognize" the test; they do not explicitly condone these uses, but neither do they advise against them. Nor does the test provider attempt to collect evidence to support the "safety" of these "unauthorized" uses. Thus, the documentation from one test lists "recognition" from organizations as diverse as universities, immigration authorities, medical, nursing and dental councils, pharmaceutical companies, laboratories and veterinary practices, charities, manufacturers from petroleum to software products, personnel agencies, financial institutions, market research and consultancy firms, airlines, tourist authorities and international trading agencies, legal practices, and the telecommunications industry. And a football club.

The nature of communication, discourse practices, and genres across this range of uses is so diverse that one test cannot meet all needs. It will inevitably be construct- and content-underrepresentative to a greater or lesser degree for all but its primary purpose, and be construct-irrelevant for many of its new uses. The language and communication needs of medical staff are not the same as pilots, tour guides, or petroleum engineers. This inconsistency of purpose leads to a state of *validity chaos* (Chalhoub-Deville & Fulcher, 2003, p. 502): it is impossible to design a validation research agenda to address the suitability of the test for all its uses. Rather, there is an unstated assumption of *validation generalizability*, that whatever evidence has been amassed for the primary purpose can be generalized to all other contexts of use. While generalizability is an important quality of scores, it refers to tasks and items within a domain that could reasonably be sampled for any form of a test (Fulcher, 2003, pp. 135–6). It does not refer to any task or item, drawn from any domain, that might allow extrapolation to different populations, contexts, discourse practices, and decisions.

As change of test purpose and use is tacitly encouraged, but potentially expensive retrofits avoided, it is not surprising that there is a paucity of published change retrofit studies. The few that are in the public domain tend to rely upon standard-setting activities to show score relevance to new uses. This approach still begs the question of construct- and content-relevance. Standard setting in itself is not enough to address change retrofit issues, and is no substitute for a robust retrofit process. To a large degree the "standard-setting fallacy" has been encouraged by the growing use of documents like the Common European Framework of Reference (CEFR). For example, if a claim is made that a level B1 on its scale is required for immigration purposes, a standard-setting activity for a test constructed for an entirely different purpose can establish a test cut score at the A2/B1 boundary; but this does not mean that the test, its content, or the meaning of the cut score, is in any way relevant, useful, or sufficient for making immigration decisions.

Indeed, there is considerable evidence to suggest that those who use off-the-peg tests do so in order to achieve policy ends, and have little concern for test purpose, score meaning, or the validity of extrapolation to their decision context (Read, 2001). The testing industry's failure to adequately document change retrofit (or admit the lack of it), while encouraging unrestricted growth in volume, is widespread. The increased use of "mediating documents" such as the CEFR merely compounds the problem. There is, however, little incentive to change a misuse that drives up test volume, and hence profit. This should be a cause for major concern, as potentially life-changing decisions are being made about many test takers on the basis of questionable reasoning, with an inadequate or nonexistent evidential basis.

The Retrofit Process

Generic guidelines for test retrofit are published by the International Test Commission (2000), but these do not foreground test purpose and construct-relevance issues. Wendler and Powers (2009, p. 6) are much more aware of the threats to inferences and decisions when a change of purpose is proposed; they recommend a careful analysis of the similarity and differences between the original and new uses, and the construction of a validity argument to justify any claim that the test will function in the same way in the new context. These activities may lead to new validation studies and a retrofitting program. Fulcher and Davidson (2009, pp. 137–9) provide a comprehensive description of the steps needed to change test purpose and carry out necessary retrofits, which include:

1. Establishing a retrofit team
2. Documenting assembly and analysis
3. Evaluation of the need and possibility of retrofit
4. Evaluation of the likely effects of a retrofit
5. Making a go/no-go decision
6. Planning the retrofit according to relevant standards
7. Establishing a research agenda to support retrofitting decisions
8. Making necessary public announcements
9. Documenting all decisions and design changes.

The purpose of crafting a deliberate retrofit plan and associated research agenda is to ensure the relevance of the test to its new purpose (or that the upgrade will be a significant improvement upon the old). It should also increase the probability that the retrofitted test is useful for making the intended decisions, that there will be few (if any) unintended postretrofit consequences, and that the inferences from test scores are sufficient (in conjunction with other available evidence) to minimize error.

Tests, like buildings, change after they are built. Some layers change very slowly, if at all, while others evolve much more quickly. Brand (1994, p. 17) writes: "The quick processes provide originality and challenge, the slow provide continuity and constraint. Buildings steady us, which we can probably use. But if we let our buildings come to a full stop, they stop us." Change is necessary and inevitable. However, it is essential that it should be purposeful, planned, audited, and open to public and expert scrutiny.

Test Specifications

FRED DAVIDSON

Introduction

A test specification (“spec”) is a generative blueprint for test items or tasks from which many equivalent test items or tasks can be produced. Specs present an operationalization of the test content, that is, they present the test in measurable terms (Davidson, Hudson, & Lynch, 1985). Test specifications are not a new concept. They have been used to control test content and ensure reliability for many decades. Arguably, Ruch coined the term (see Ruch, 1929, p. 150), and even earlier, he presents guiding language for multiple-choice tests in Ruch (1924, pp. 95–9).

Specs can be written at different levels of generality, from an overarching view of test content to a highly detailed and rich description of an individual item or task (Davidson & Lynch, 2002, pp. 11, 53–7). Specs evolve over time and enhance test validity as shown conceptually in Figure 1; the number of steps and revisions shown in this figure are conceptual, and the actual amount of revision will vary in each test development situation.

2 TEST SPECIFICATIONS

Changes to test specs depend on feedback, which is of two types: (a) expert review and discussion of the specs, and (b) empirical data from test tryouts and operational use. If the spec documents go through successive versions, the whole process can be audited to present a validity narrative (Davidson & Lynch, 2002, p. 9; Li, 2006).

The Sources of Test Specifications

Test specs originate from many influences. Theories of language learning and teaching affect the design and content of test specs. For example, a teaching institution may have a daily schedule of four contact hours, each dedicated to the four language skills. Logically, the entry and placement test for that institution would be divided into four parts (reading, writing, listening, and speaking), and this division would be evident in the structure of the test specs. Another influence on the origin of test specs is logistics and budget. For example, a language-teaching institution may be facing sudden and unanticipated growth in its student population. This growth puts strain on the existing entry and exit testing, and so the institution (perhaps against its teachers' best wishes) is forced to make sacrifices, such as elimination of some rated assessment in favor of machine-scorable tests.

Davidson and Lynch (2002, chap. 5) propose a name for the constellation of contextual forces that shape the design of test specifications: the mandate. The design and layout of test specs responds to the mandate, and hence, there (really) is no standardized layout of a specification. If the mandate includes strong influences about language theory, then the structure of the spec may reflect that theory. If, on the other hand, the context allows teacher latitude in pedagogical practice, the specs may seem rather atheoretical. At the end of the day, all styles of detailed specs share but two things in common: they present sample(s) of the items or tasks that the spec is intended to generate and they provide guiding language about those samples (Fulcher & Davidson, 2007, pp. 54–5).

Examples of Test Specifications

An example of a highly general set of specs is given in Table 1—this would be accompanied by sample items or tasks; that is, the test booklet itself.

Table 1 provides little guidance about how to measure each skill. It is (essentially) an organizational tool that states how many items of each type are needed. It is likely that richer specs will also be necessary for this test situation, most likely, at least one detailed spec per row. The balance of this entry concerns such detailed specs, for that is where the true generative power of test specification is realized.

Table 1 A sample table of specifications (adapted from Davidson & Lynch, 2002, p. 66)

<i>Skill tested</i>	<i>Number of tasks/items per skill</i>	<i>Type of task/item per skill</i>	<i>Special materials and comments</i>
Vocabulary in context	20 items	Multiple choice with formulaic stem	Passages needed; 2–3 items per passage
Scanning	20 items	Multiple choice: specific information from passage	Passages needed; 2–3 items per passage
Skimming	20 items	Multiple choice: general information from passage	Different passages from scanning; 1–2 items per passage

The following is a detailed specification for testing vocabulary. This example serves two purposes. First, it illustrates the typical level of detail necessary in generative test specifications, and second, it illustrates the nature of feedback in test development (because it is not yet refined):

Spec Title: Testing Vocabulary in Context

This spec is intended for use in an ESL/EFL teaching situation in which the students need to figure out the meaning of words from contextual cues. The output of this spec is a multiple-choice item, in which the selection of the correct answer depends on information found elsewhere in a body of text.

The stem of the item should follow a set formula: "As used in line XX, the word 'YYYYYY' means." The best choice should be directly discernible from the text, and should be given as choice (c) (Choice order will be randomized before assembly of the full test).

Distracters (a) and (b) should be a known and plausible meaning of the target word but one that is irrelevant to the text as presented. Distracter (d) should refer to word or concepts elsewhere in the text but present an implausible meaning of the target word.

Up to three items can be generated for a given text.

The text should be 50–200 words at an intermediate difficulty level. The topic should be a familiar concept, thing, place, or person; however, some specialized knowledge or exposition is permitted (so that contextual vocabulary cues can be obtained).

Sample Text (retrieved December 1, 2009 from <http://en.wikipedia.org/wiki/Handcycle>):

1. A handcycle is a type of human powered land vehicle powered by
2. the arms rather than the legs, as on a bicycle. Most handcycles
3. are tricycle in form, with two coasting rear wheels and one
4. steerable powered front wheel.
5. Many manufacturers have designed and released hand-powered
6. recumbent trikes, or handcycles. Handcycles are a regular
7. sight at HPV meets and are beginning to be seen on the streets.
8. These usually follow a delta design with front wheels driven by
9. standard derailleur gearing powered by hand cranks. Brake levers
10. are usually mounted on the hand holds, which are usually set
11. with no offset rather than the 180° of pedal cranks. The entire
12. crank assembly and the front wheel turn together, allowing the
13. rider to steer and crank simultaneously.
14. Thanks to modern technology, handcycles come in a variety of
15. styles, making them accessible to people of all abilities,
16. including many persons with disabilities. There are also
17. hybrids between a handcycle, a recumbent bike and a tricycle.

Sample Item One:

As used in line 7, the word "HPV" means:

- (a) hand project version
- (b) hand propelled variation
- (c) human-powered vehicle
- (d) hand-propelled vehicle

4 TEST SPECIFICATIONS

Sample Item Two:

As used in line 12, the word “assembly” means:

- (a) a gathering of people
- (b) a gathering of bicycles
- (c) a handcycle’s pedal mechanism
- (d) a bicycle’s pedal mechanism

This test specification is at an early developmental stage and would probably not even merit a conceptual “Version 0.25” as shown in Figure 1. Before it becomes operational, feedback about a number of problems is needed through discussion or trial or both:

1. Sample Item One does not test a word; it tests an abbreviation. Is this desirable?
2. The spec requests a passage that presents a familiar topic, but it allows some specialized knowledge. Is this sample text acceptable with regard to topic familiarity, or is it too specialized? Should the spec have additional guiding language that clarifies the permissible boundaries of specialized knowledge for the passage?
3. There is no guidance on the overall difficulty level of the passage. What is the teaching context? If these items are going to be used at a particular instructional level, does this text represent the kind of reading activities typical at that level?
4. Distracters (a) and (b) can refer to plausible meaning outside of the text. Only distracter (d) is designed to capture a plausible in-text meaning. If the item really tests contextual vocabulary, should this proportion be changed, such that there are two in-text plausible distracters and only one that refers to extra-textual meaning? Alternatively, should all three distracters be plausible in-text meaning?
5. What is the meaning of “plausible,” both inside and outside of the text? For instance, is choice (d) in each sample item doing roughly the same thing?
6. Does the sample text and each sample item really tap into contextual clues, or might the test taker use real-world knowledge? How can this be controlled? Some vocabulary-in-context tests use nonsense words instead of actual language. Is that a viable alternative?
7. What does it mean that the best choice is “directly discernible” from the text? Precisely what analytical steps does the test taker follow in order to figure out the meaning of the target word?

The spec is probably not yet ready for tryout, although even at this early stage some informal piloting may help, particularly if it is done in a focus-group style so that the test takers can give direct feedback right after the questions are answered. The spec certainly is not yet ready for operational and productive use. The spec needs feedback, and further discussion and consensus building are necessary. This discussion would trigger changes to the spec, and it can evolve from one version to the next, as shown in Figure 1.

The Evolving Nature of Test Specifications

Such evolution is where specification-driven test development really contributes to validity. At the beginning of the life of any detailed test spec (e.g., a conceptual version 0.10, in which this vocabulary item might reside), the focus of the spec is in a state of creative chaos. As time progresses and feedback comes in, the testers come to an agreement about what they wish to measure, and how they wish to measure it. It is very important to delay a rush-to-production if at all possible. Instead, test developers should grant sufficient time for debate and (if logistically feasible) tryout.

It may seem that developing detailed test specs is a time-consuming process. Spec writing can be streamlined through reverse engineering, which is the production of a test specification

from existing items or test tasks. For example, in a content-based language-teaching situation, the following test question might be on file:

After oxygen, silicon is the most common chemical element found in combination in the rocks that make up the Earth's crust. Very few people, however, have ever seen pure silicon. That is true not because silicon is invisible, but because it is usually found in combination with other elements.

What does the passage say about pure silicon?

- (a) It is useful.
- (b) It is rarely seen [this is the intended correct choice].
- (c) It is like oxygen.
- (d) It is invisible.

(Retrieved December 10, 2009 from www.bhcc.mass.edu/inside/687)

The teachers could analyze this item and begin to write guiding language for it, such as:

This item type focuses on reading of academic scientific language. A three-sentence factual paragraph is followed by a multiple-choice question. The first sentence presents some general truth or state. The second presents some unusual fact associated with the first. The third explains why that fact is unusual. The multiple-choice question tests direct close reading of the unusual fact. The distracters present misreadings of other facts or assertions elsewhere in the paragraph.

This is called "straight" reverse engineering, for which the goal is to generate equivalent test items. It is also possible to do "critical" reverse engineering, during which the original test item might be improved (Fulcher & Davidson, 2007, p. 57).

Another way to streamline specification-driven test development is to use archetypes, which are extremely common item or test tasks (Fulcher & Davidson, 2007, pp. 58–9). For example, if a group of teachers gather and wish to write a test item about careful reading of scientific myth-dispelling language (like the previous example), they might realize that they all have the same kind of item in mind: one in which a short passage is followed by a multiple-choice test question. Archetypes are beneficial because they represent common item types that are familiar to all: teachers and students alike. However, such familiarity may lead a test development team away from true innovation and in some instances can stifle creativity in test design.

In any test spec, the sample item or task fulfills an extremely important role; in effect, the sample item is the archetype. Guiding language alone cannot generate tests. This is particularly true in tests that yield constructed discourse, for example, an essay, or in tests for oral interviews and other face-to-face test settings. The sample may involve actual examples of student performance: sample student essays or recordings of a previous oral test.

The sample specs illustrated in this entry have been for multiple-choice testing. If the student selects the correct response, then (typically) a single point is awarded, and the test score is the sum of those points. Specs can also be used to describe constructed response tests such as an essay exam or an oral interview. In those cases, the spec typically also includes a rating scale (or refers to an existing external rating scale).

Test Specifications and Constructs: An Illustration

Test specifications encourage test developers to discuss the construct at a very productive and detailed level of dialogue, and such a discussion may lead to insights about theory and pedagogy. For example, in the vocabulary spec, comment (5) about plausibility raises

intriguing problems of theory. The test developers may quickly agree on an existing definition of “plausibility” that they all share. Perhaps it is a simple everyday meaning like “reasonable and sensible” (retrieved December 10, 2009 from www.urbandictionary.com). Perhaps the teachers realize that the everyday meaning is not suitable for the linguistic nature of text-based semantics, and so they need to clarify what that term means in their guiding language. They might borrow the phrase “reasonable and sensible” but elaborate it in language such as: “as related particularly to this passage” or “as related particularly to this passage, and excluding meanings of the word not pertinent to this passage.” For the purposes of this entry, it is not really relevant what “plausible” means. The point is to illustrate the productive and detailed debate that happens naturally as specs evolve. This discussion takes time and eventually even includes both negative and positive guiding language and examples (i.e., in a later version of the spec, they might show examples of what is and what is not a plausible distracter). Once the spec reaches an overall point of consensus, they can look back at the evolution of a difficult but crucial term (like “plausible”) and document how their evolved understanding of that term—bolstered, perhaps, by trial data—arrived at consensus and stability. Doing so is an “audit” of a test spec (Davidson & Lynch, 2002, p. 9; Li, 2006). The audit helps to document validity not only of the test but of difficult theoretical notions that underlie the test.

What is more, the test developers might discuss and debate a tricky term—like “plausible”—in light of their experience in language classrooms. They might recall and document the kinds of mistakes and successes that their students display in decoding meaning from text. Perhaps that is what triggered the test spec in the first place; the classroom experiences may have been a large element of the “mandate” for the exam (Davidson & Lynch, 2002, chap. 5). Perhaps these teachers have discovered that students tend to look for discourse clues in a very narrow range of text, and so they might define “plausible” to mean: “reasonable and sensible as determined across the entire text.” If they do this, then the test developers are engaging in effect-driven test development, which is an approach to testing that draws from the philosophical school of classical pragmatism. Effect-driven pragmatic testing operates from the simple precept that the nature of a thing lies in its effect or outcomes. In test development, such a view can enhance washback (Fulcher & Davidson, 2007). If the test developers think first and foremost about the effects that they wish to see, then they can shape their test to achieve that outcome, and they can better build a link between teaching and testing. This perspective works best if it is done at the level of a test spec, so that the test developers not only resolve difficult terminology and concepts but ensure that the sample items and tasks represent the resolution on which they all eventually come to agree.

Concluding Remarks

The best way to learn about specification-driven language test development is to work with a test spec over time and see how it changes and evolves. This entry has attempted to capture that experience and provide something that can be read and studied, hopefully of value, but not in itself dynamic. The reader is strongly encouraged to try out the dynamic nature of test specifications through application to his or her own language-teaching context.

Testing in Pragmatics Research

CARSTEN ROEVER

It may seem contradictory to talk about “testing” in the context of “research”: after all, testing in a narrow sense is usually done to collect evidence for real-world decisions and involves stakes for all parties involved in the process, and tests therefore need to be based on a carefully designed interpretive validity argument (Messick, 1989; Kane, 2006; Bachman & Palmer, 2010), which in itself requires a fairly extensive research program. However, testing in a simpler sense is the measurement of the strength of an attribute, which does not necessarily have to be the basis for a high-stakes decision. Rather, it might be undertaken to answer a research question; for example, to evaluate the effectiveness of an instructional intervention intended to improve learners’ knowledge or skills, trace learners’ development in language abilities over time, or compare participants with each other who differ in theoretically interesting background variables, such as proficiency level, gender, native language, or study-abroad experience.

It is the latter type of testing, which is intended to ascertain the degree to which learners have a certain type of knowledge or skill, which will be discussed here. This entry will start out by delineating some criteria of test quality, which are relevant to any type of test, and then describe some testing approaches used in second language (L2) pragmatics research.

Criteria of Test Quality

The overriding criterion of test quality is validity, which can be defined as “an integrated evaluative judgment of the degree to which empirical evidence and theoretical rationales support the *adequacy* and *appropriateness* of *inferences* and *actions* based on test scores or other modes of assessment” (Messick, 1989, p. 13; emphasis in original). This definition highlights the fact that validity resides in conclusions and decisions rather than in test items: A test is not in itself valid or invalid. Rather, the interpretations or conclusions from test scores may be more or less valid, which we can gloss as “defensible” or “reasonable.” For tests used for research purposes, such conclusions are frequently answers to theoretically based research questions; for example, whether learners in the English as a second language (ESL) environment have higher pragmatic than grammatical awareness (Bardovi-Harlig & Dörnyei, 1998), whether a study-abroad experience leads to more target-like judgments of social relationships (Matsumura, 2001), whether a certain type of instruction is more effective than another or no instruction (Takimoto, 2009), or whether proficiency affects learning of implicature more than exposure (Bouton, 1999; Roever, 2005).

Messick (1989) identifies two major threats to validity: construct underrepresentation and construct-irrelevant variance. Construct underrepresentation describes a situation where the test taps only a certain subset of ability or knowledge but inferences are drawn across a much wider domain. For example, a test that assesses only learners’ comprehension of implicature but whose scores are used to make claims about their overall pragmatic competence would be underrepresenting the construct. Conversely, construct-irrelevant variance describes the influence of confounding factors that are not the focus of assessment, such as the effect of learners’ reading proficiency when taking a test on speech acts.

2 TESTING IN PRAGMATICS RESEARCH

In high-stakes tests, decisions based on score interpretations need to be supported by an argument demonstrating the defensibility of the scoring system, interpretations of scores, and decisions based on scores (Kane, 2006; Bachman & Palmer, 2010). While a carefully constructed interpretive argument requires a number of validity studies which would be beyond the reach of most researchers designing tests for research purposes, some fundamental markers of quality apply equally to any test. For conclusions to be defensible, a test must be

- reliable—it measures precisely;
- standardized—all test takers do the same or equivalent tasks, they all get scored following the same criteria, and performances are comparable;
- authentic—the tasks elicit performances that test takers would also display in real-world interactions;
- construct-relevant—the tasks cover the target domain and neither underrepresent the construct nor are contaminated by construct-irrelevant variance; and
- practical—the test uses resources sparingly, which makes it more likely to be employed.

The following section will briefly discuss some tests that have been developed as assessment instruments in L2 pragmatics research, and which can serve as models for the design of tests for research purposes.

Tests of L2 Pragmatics

Some tests have been developed in L2 pragmatics research for the explicit purpose of providing a basis for decisions, but none has so far been used large-scale. The first major test development project was Hudson, Detmer, and Brown's (1995) test battery for Japanese ESL learners. Their tests focused on the speech acts of request and refusal and consisted of oral, written, and multiple-choice discourse completion tests (DCTs), a role play, and two self-assessment scales. The test was designed as a general proficiency test and led to a good deal of research and several spin-offs (Yamashita, 1996; Yoshitake, 1997; Brown & Ahn, 2011; Liu, 2006).

The second larger assessment project was Roever's (2005, 2006) test, which also contained a DCT section but in addition assessed learners' recognition of situational routine formulas and the comprehension of implicature through multiple-choice tasks. Roever (2005) reports on the validation of his test using Messick's (1989) approach, and underscores the close connection between assessment and research by showing that in the course of conducting validity studies, new research findings emerge, such as the central role of L2 proficiency for comprehending implicature (Roever, 2005), or existing ones are confirmed, such as the superiority of learning routine formulas in the target language environment (Roever, 2005, *in press*).

Tests designed for research purposes do not generally follow such wide-ranging and rigorous validation procedures as the instruments described above, but their claims also tend to be much more limited, and usually focus on a particular aspect of pragmatic knowledge or ability for use.

Measuring Performance

Test instruments in pragmatics research can be placed on a continuum from tests eliciting online, real-world equivalent performance to tests eliciting offline knowledge.

The most performance-oriented measure is observation of learners in natural interactions. This is, however, logistically complicated and ethically problematic as it requires unobtrusive and even covert observation. Standardization is difficult if learners are simply taped in a wide variety of interactions since interlocutor reactions and the type of interaction cannot be controlled. On the other hand, such an approach would provide the most persuasive data and enable defensible claims about learners' ability to use pragmatics in actual interaction. Two studies have used authentic discourse data, and dealt with the problem of standardization by focusing on one type of institutional interaction. Bardovi-Harlig and Hartford (1996) recorded academic advising sessions, and compared non-native and native speakers' performance in an early and a later session. The authors analyzed suggestions and rejections of suggestions by the students, as well as the content used in both, comparing frequencies between groups and across time. Similarly, Al-Gahtani (2011) investigated learning of requests by learners of Saudi Arabic at four proficiency levels who interacted with an administrator at two data collection points five months apart. The learners were not aware at the time that they were part of a research study. Al-Gahtani coded requests for head acts and internal and external modifications (Blum-Kulka, House, & Kasper, 1989) and also analyzed the sequential organization of the interaction (following Schegloff, 2007). He found very little change over time but distinct differences between proficiency groups. Neither study is a "test" in the traditional sense of scoring learner performance, but both employed a native-speaker baseline and compared average learner performance with average native-speaker performance to find evidence of development or differences between proficiency groups.

A more standardized but less authentic method is collection of role-play data, which has been used quite frequently in pragmatics research. Role plays allow a certain degree of standardization through the role-play instructions, and where they are carried out with trained role-play conductors (rather than between participants), the conductor can also follow behavioral guidelines in how to interact with the participant. However, role plays are not identical to natural interactions (Aston, 1993) and therefore lack authenticity, since participants are aware that they are being evaluated and that it is specifically their language that is in focus. Okada (2010) argues that despite this shortcoming participants need to make use of the same resources they would rely on in natural conversation, but it is unclear how exactly the role-play situation affects production in terms of sequential organization of interaction.

Role plays have been widely used in interlanguage pragmatics research to investigate speech acts such as request (Taguchi, 2006), apology (Trosborg, 1995), refusal (Félix-Brasdefer, 2004), and complaint (Trosborg, 1995), as well as gambits and routine formulas (House, 1996). For example, Taguchi (2006) compared the performance of requests by Japanese ESL learners at two proficiency levels and a group of native English speakers. She rated the participants' requests for appropriateness and coded them according to the Cross-Cultural Speech Act Realization Project (CCSARP) (Blum-Kulka et al., 1989) coding scheme. While Taguchi did not investigate the conversation around the requestive head act, Félix-Brasdefer (2004) compared refusals by learners of Spanish with different length of residency and included English and Spanish native-speaker data. He also coded strategies, but took other discursive moves into account as well. In a rare primarily interactionally focused study, Al-Gahtani and Roever (2011) investigated differences in requestive interactions between four proficiency groups of ESL learners using the tool set of conversation analysis. These authors found a greater occurrence of pre-sequences and less interlocutor involvement at the higher proficiency levels, as well as indications that only high-proficiency learners were taking the situational context into account. Role-play performance is rarely scored, although Takimoto (2009) is an example; this study scored learner production for

appropriateness, abbreviating Hudson et al.'s (1995) much more detailed scoring system, which involved six criteria. No study has scored other aspects of the interaction, such as the need for interlocutor repair moves, learner versus interlocutor control of the interaction, and pre- and post-sequences surrounding the head act.

Both authentic conversation and role plays are low on practicality and difficult to standardize, and there are no statistical procedures for evaluating their reliability. However, both offer authentic data if production and performance are the focus of the research, and they allow the investigation of interactive abilities, which are outside the reach of measures eliciting offline knowledge. We will now turn to these.

Non-Performance Measures

Probably the most widely used testing instrument is the DCT, recently, for example, for investigating requests (Woodfield & Economidou-Kogetsidis, 2010), refusals (Wannaruk, 2008), apologies (Warga & Scholmberger, 2007), and others (Barron, 2007). DCTs elicit offline knowledge about speech acts, that is, what participants think they would say in the situation described in the prompt. These tests do not allow claims about performance or interactive abilities and are therefore most appropriate in research situations where the goal is the elicitation of isolated speech acts, such as initial greetings, compliments, or expressions of gratitude. DCTs have strong logistical advantages in that they allow researchers to systematically vary contextual variables like power, social distance, or degree of imposition, enable systematic sampling of participants by background variable of interest (e.g., proficiency level, native language, length of residence), and facilitate the simultaneous collection of large amounts of data, even through research confederates or via the Internet. In their common written format, DCT responses do not require time-consuming transcription (although oral DCTs do), and since all participants respond to the same prompts, DCTs appear to have a high degree of standardization. However, the latter claim is problematic, as it is difficult to ensure that all participants interpret the DCT prompt in the same way.

Scoring of DCT responses is unusual in pragmatics research, where the focus is primarily on describing the differences between participants in terms of strategy use. However, where DCT responses are scored, scoring usually relies on a rating scale to quantitatively express appropriateness judgments. For example, Takimoto (2009) had two raters score the appropriateness of DCT responses on a request DCT using a scale of 1–5. He obtained a near-perfect correlation between raters (.995) but does not report absolute agreement or the more common index of Cohen's kappa. He then used two-way repeated measures ANOVA and line graphs to investigate the effect of instruction by comparing pretest, posttest, and follow-up scores of four groups. Employing scoring of responses allowed him to run such complex statistics, which would not have been possible using simple frequency measures.

A special case of DCTs are multiple-choice DCTs, where participants choose the "most appropriate" utterance from among three to four response options. This type of instrument elicits sociopragmatic judgment and does so more directly than written or spoken DCTs, in which learners' general L2 proficiency can introduce construct-irrelevant variance. Multiple-choice DCTs are also highly practical as scoring can happen entirely automatically, and they have been used in effect-of-instruction studies (Koike & Pearson, 2005) and to document the effects of exposure in study abroad (Matsumura, 2001). However, they are problematic instruments. Hudson et al. (1995), as well as Yamashita (1996), found low reliabilities on their dichotomous multiple-choice DCTs, the central problem being that it was very difficult to design clearly incorrect distracters that were not acceptable to at least some native speakers. Both Liu (2006) and Matsumura (2001) also found low levels

of native-speaker agreement in their multiple-choice DCT, but Matsumura circumvented this problem by using partial-credit scoring, that is, assigning four points to the answer chosen by the majority of native speakers, three points to the answer chosen by the second largest group, two points to the answer favored by the next largest group, and one point to the answer chosen by the smallest group of native speakers. Such an approach is highly problematic from a construct perspective, however, since it implies that some answers from the native-speaker benchmark group are better than others, and converts interval-level data to ordinal-level data, thereby distorting differences in degree of preference between responses.

Another approach to eliciting sociopragmatic (acceptability) judgments is to have learners judge the characteristic of a target exemplar in context, usually by means of a rating scale. For example, Bardovi-Harlig and Dörnyei (1998) pioneered a video-supported acceptability rating task, in which learners were shown a brief conversation whose final utterance contained either a grammatical error, a pragmatic infelicity, or no error. Learners were then asked to judge the target utterance on a scale ranging from "not bad at all" to "very bad." Bardovi-Harlig and Dörnyei found significant differences in degree of acceptability judgments between pragmatic infelicities (rated as more serious by their ESL population), and grammatical errors (rated as more serious by their English as a foreign language [EFL] population). It is notable that a native-speaker baseline was not an issue for the scoring of responses, because these authors were interested in learners' impressions of the relative importance of socially appropriate and grammatically correct language use and how these impressions would be influenced by the learning context.

Takimoto (2009) used a magnitude estimation approach for his acceptability judgments, where learners judged the first item on an 11-point scale and the following items in relation to this anchor item. He scored learner judgments using a partial-credit approach based on a native-speaker baseline, but does not provide details on how this was done. Cook (2001) also used acceptability judgments, but took a different theoretical perspective. She investigated learners' ability to recognize appropriate speech styles in Japanese as a foreign language by asking them to identify which of three tape-recorded self-introductions would be appropriate for an applicant in a job interview.

Finally, a number of knowledge-oriented tests have not focused on speech acts and appropriateness. Bouton (1999) pioneered a multiple-choice instrument assessing comprehension of ESL implicature and traced learners' changes over time, claiming that some types of implicature are learned through exposure whereas others require instruction. However, Roever (2005) showed that it was increases in learners' proficiency rather than pure exposure that contributed to their development of implicature comprehension. Taguchi (2008) added measurement of reaction time to L2 implicature research, opening up an interesting and as yet under-explored dimension of L2 pragmatics research.

Another area where testing has taken place is routine formulas. They were part of Roever's (2005, 2006) assessment battery, and Roever (in press) used data from the original assessment study to show that some routine formulas can be learned outside the target language context, others are acquired very quickly in the target language context, and others take much longer to be learned even for learners with a high degree of exposure. Bardovi-Harlig (2009) tested routine formulas productively through a DCT-type instrument designed to elicit a formula. She found an interesting relationship between grammatical ability and production of formulaic expressions, indicating that even with these highly standard expressions, general proficiency plays a role.

Multiple-choice and brief-response measures that are clearly referenced against a native-speaker benchmark (though this is of course problematic in itself; see Kasper, 1995) might look the most like "tests" since they are highly standardized, allow reliability computations, and are highly practical. However, their construct coverage is relatively small,

allowing conclusions only about learners' judgment or knowledge but not about their ability for use. Researchers and consumers of research need to be aware of the limited reach of these studies, which have very little to say about learners' ability to use language in context.

Summary

Testing in pragmatics research is primarily done to discern the effects of instruction, study abroad, and in some cases general proficiency. As the instruments used for research purposes do not carry stakes for participants, there is rarely any rigorous validation process involved, in contrast to the development of test instruments for formal assessments. While the expenses associated with a large-scale validation study are outside the reach of smaller research studies, evaluating tests for research purposes as to their validity is important for assessing the quality of L2 pragmatics research studies.

The future of this area will need to see an increase in performance measures. While non-performance measures show whether learners have the pragmatic knowledge necessary for real-time language use, it is of far greater relevance to find out how and to what extent learners actually implement their knowledge in using the target language. While performance measures like role plays can provide evidence of learners' ability for use, they tend to be resource-intensive and difficult to standardize, so future methodological research will need to find ways to ensure comparability across participants while keeping the interaction as authentic as possible. Exploring the use of technology for simulating interactions and investigating how such simulations compare to role-played and real-world talk will also need to be a central area of research.

Testing Independent Relationships

STEFAN TH. GRIES

In one of the most frequent empirical scenarios in applied linguistics, a researcher's empirical results can be summarized in a two-dimensional table, in which

- the rows list the levels of a nominal/categorical variable,
- the columns list the levels of another nominal/categorical variable, and
- the cells in the table defined by these row and column levels provide the frequencies with which combinations of row and column levels were observed in some data set.

An example of data from a study of disfluencies in speech is shown in Table 1, which shows the parts of speech of 335 words following three types of disfluencies. Both the part of speech and the disfluency markers represent categorical variables.

Table 1 shows that 30 *uh*'s were followed by a noun, 20 *uhm*'s were followed by a verb, etc. One question a researcher may be interested in exploring is whether there is a correlation between the kind of disfluency produced—the variable in the rows—and the part of speech of the word following the disfluency—the variable in the columns. An exploratory glance at the data suggests that *uh* mostly precedes conjunctions while silences most precede nouns, but an actual statistical test is required to determine (a) whether the distribution of the parts of speech after the disfluencies is in fact significantly different from chance, and (b) what preferences and dispreferences this data set reflects. The most frequent statistical test used to analyze two-dimensional frequency tables such as Table 1 is the chi-square test for independence.

The Chi-Square Test for Independence

The chi-square test for independence is introduced by describing how data analysis is conducted using the open source statistical language and environment R (R Development Core Team, 2010), which can be freely downloaded from <http://cran.at.r-project.org> and which runs on all major operating systems.

Entering the Data

The first step in the analysis of two-dimensional frequency tables is to start the R program and enter the frequency table into R. For example, to enter the above data in Table 1, the

Table 1 Fictitious data on the correlation of DISFLUENCY and PART OF SPEECH 2

	<i>Noun</i>	<i>Verb</i>	<i>Conjunction</i>	<i>Totals</i>
<i>uh</i>	30	70	90	190
<i>uhm</i>	50	20	40	110
silence	20	5	10	35
Totals	100	95	140	335

DOI: 10.1002/9781405198431.wbeal1202

2 TESTING INDEPENDENT RELATIONSHIPS

researcher would type the following at the console prompt (where `c` means “combine values into a vector, or sequence,” `ncol` specifies the number of columns into which the sequence of numbers should be coerced, `<-` represents an assignment arrow, and the Pilcrow sign ¶ means “press ENTER”):

```
x <- matrix(c(30, 50, 20, 70, 20, 5, 90, 40, 10), ncol=3)¶
```

This creates the matrix of the frequencies shown in Table 1 and stores it as an object called `x`. However, since this matrix does not yet have row and column names, it is useful to add such names using the function `list`. This function takes two vectors, first the row names, second the column names:

```
attr(x, "dimnames") <- list(Disfluency=c("uh", "uhm", "silence"),  
POS=c("Noun", "Verb", "Conjunction"))¶
```

If one now tells R to display the object `x`, then the data are shown nearly exactly as represented in Table 1:

```
x¶  
      POS  
Disfluency Noun Verb Conjunction  
uh         30   70           90  
uhm        50   20           40  
silence    20    5           10
```

If one needs the row and column totals of `x`, too, then these can be obtained from the function `addmargins`:

```
addmargins(x)¶  
      POS  
Disfluency Noun Verb Conjunction Sum  
uh         30   70           90 190  
uhm        50   20           40 110  
silence    20    5           10  35  
Sum        100   95          140 335
```

Assumptions

The second step involves determining whether the data are such that one can in fact compute a chi-square test for independence. This test has three assumptions of two different kinds: the first two have to do with the frequencies that would be expected if the data were randomly distributed; the third has to do with whether the data points are independent of each other or not. The three assumptions are the following:

- 80% of the expected frequencies are greater than 4;
- all expected frequencies are greater than 1; and
- all observations are independent of each other.

In R the first two assumptions are best tested with the function of the chi-square test itself, but the third assumption requires the researcher to consider whether data points—individual occurrences of a disfluency with the part of speech of the following word—are related to each other. This would be the case if, for example, one and the same speaker

provided more than one data point to the data set. In such a case, an individual speaker's preference for a particular disfluency, or a particular disfluency before some part of speech, could bias the statistical evaluation of the data. Another threat to independence could arise if disfluencies were from different speakers but from successive turns in the same conversation, because then a disfluency in turn t might be influenced by the one in turn $t - 1$ because of priming effects. We will assume that this is not the case here because, for instance, each collected disfluency is from a different speaker in a different conversation.

Testing the assumptions of the chi-square test is important because, when the data violate the assumptions of the test, its results cannot be trusted: If (too many) expected frequencies are too small, then the test becomes anti-conservative and may return a significant result although the null hypothesis is correct, and if the data points are not independent of each other, then the computation of the expected frequencies will be biased. Making sure that the test's assumptions are met is therefore paramount.

Computing and Significance Testing

If the assumptions of the chi-square test are met, it can be computed very easily in R. The function for the chi-square test is called `chisq.test`, and it takes two arguments: the table for which one wants to compute a chi-square test (here: `x`), and an argument `correct` that is set to `TRUE` or `FALSE`, depending on whether or not one wants to use a so-called continuity correction, which is sometimes recommended for sample sizes between 20 and 60 and which will therefore not be needed for this example. The researcher assigns the result of the chi-square test to an object `x.test`:

```
x.test <- chisq.test(x, correct=FALSE)¶
```

Nothing is returned, but the data structure `x.test` now contains all the results. Three things must now be done. First, the researcher should inspect the frequencies that would have been expected by chance—that is, when there is no correlation between the kind of disfluency and the part of speech of the following word—by calling the part of the test results that contains the expected frequencies:

```
x.test$exp¶
      POS
Disfluency  Noun      Verb  Conjunction
uh          56.71642  53.880597    79.40299
uhm         32.83582  31.194030    45.97015
silence     10.44776   9.925373    14.62687
```

(One can also compute each expected frequency of a cell manually by dividing the product of the cell's row and column total by the total of the table, for example, $190 \cdot 100 \div 335 = 56.71642$, and so forth.) Obviously, all expected frequencies are greater than 4 so the application of the chi-square test is justified. Therefore, the second step is to determine whether the observed result from Table 1 is significant—that is, different enough from the expected result shown above—by calling the overall result:

```
x.test¶
      Pearson's Chi-squared test
data:  x
X-squared = 45.2273, df = 1, p-value = 3.566e-09
```

4 TESTING INDEPENDENT RELATIONSHIPS

In this example, there is a highly significant correlation between the kind of disfluency and the part of speech that follows: p is much smaller than the critical value of $p = 0.05$ that is usually adopted in the social sciences: $3.566\text{e-}09 = 3.566 \cdot 10^{-9} = 0.000000003566$. However, the fact that there is an overall significant result does not reveal which of the nine cells is/are most responsible for this effect, i.e. what to focus on most in the interpretation. To identify these cells, one can inspect the so-called Pearson residuals.

```
x.test$res[[
  POS
Disfluency      Noun      Verb  Conjunction
uh             -3.547512   2.196002   1.1892280
uhm            2.995361  -2.004245  -0.8805362
silence        2.955245  -1.563384  -1.2097935
```

If the Pearson residual in a cell is positive, then the observed frequency in that cell is greater than the expected frequency in that cell, and if the Pearson residual in a cell is negative, then the observed frequency is less than the expected frequency. The more the Pearson residual deviates from 0, the stronger that effect. In this case, therefore, the strongest effect is the dispreference of *uh* before nouns (observed frequency: 30, expected frequency: 56.7), followed by the preferences of *uhm* and silences before nouns (observed frequencies 50 and 20, expected frequencies 32.8 and 10.4 respectively). By contrast, the Pearson residuals for conjunctions are closer to zero, since their observed frequencies are closer to the expected ones.

Graphical Interpretation and Effect Size

The above kind of interpretation of chi-square tests can often be facilitated considerably with graphical displays. Figure 1 shows two frequent plots, which can be created with the following two lines:

```
mosaicplot(t(x))
assocplot(t(x))
```

The left panel shows a so-called mosaic plot, in which the box sizes are proportional to the cell frequencies and where the lack of alignment of the margins between the boxes indicates correlational structure; for example, compare the small box of *uh*:Noun against the long box for *uh*:Verb. The right panel shows a so-called association plot, in which dark and light gray rectangles indicate observed frequencies greater and less than the expected frequencies respectively, and in which the area of the box is proportional to the difference in observed and expected frequencies. It is therefore easy to see that the significant effect is mostly due to the fact that *uh* is less likely before nouns and more likely before verbs and conjunctions, and that *uhm* is less likely before verbs, and so forth.

Finally, in order to be able to compare results from different studies, one needs to compute an effect size, which is independent of the sample size. For two-dimensional tables, a statistic called Cramer's V is used. It falls between 0 ("no association") and 1 ("perfect association") and is computed as shown in (1), where $\min(r,c)$ means "take the numbers of rows and columns (here, each is three) and pick the smaller of the two":

$$(1) \quad V = \sqrt{\frac{\chi^2}{n \cdot (\min(r,c) - 1)}}$$

Figure 1 A mosaic plot (left panel) and an association plot (right panel) for the data in Table 1

In this example, the effect size can be computed with the following code, where `sqrt` means “square root,” `x.test$stat` represents the chi-square value of the chi-square test stored in `x.test`, `sum(x)` represents the sample size n , and `dim(x)` returns the numbers of rows and columns of the data table `x`, of which then the minimum (`min`) is taken. The resulting Cramer’s V value is relatively small, certainly much closer to 0 than to 1:

```
sqrt(x.test$stat/(sum(x) * (min(dim(x))-1)))  
X-squared  
0.2598142
```

To report the result of a chi-square test, the researcher should provide the table of observed frequencies, the chi-square value as well as its df , its p -value, and the effect size. The next section discusses very briefly one way to proceed if the expected frequencies are too small to use the chi-square test, namely an exact test.

An Exact Alternative: An Exact Test for Independence

Sometimes, one may not have data that result in expected frequencies large enough to meet the conditions of the chi-square test. For instance, one may have obtained only 20% of each cell’s frequency in Table 1, as in this table `y`.

```
y <- x/5  
y  
      POS  
Disfluency Noun Verb Conjunction  
uh          6   14         18  
uhm         10    4          8  
silence      4    1          2
```

A chi-square test on `y` shows that more than 20% of the expected frequencies are smaller than 3:

6 TESTING INDEPENDENT RELATIONSHIPS

```
chisq.test(y, correct=FALSE)$exp
      POS
Disfluency      Noun      Verb Conjunction
uh          11.343284  10.776119   15.880597
uhm           6.567164   6.238806   9.194030
silence       2.089552   1.985075   2.925373
chisq.test(y, correct=FALSE)
      Pearson's Chi-squared test
data:  y
X-squared = 9.0455, df = 4, p-value = 0.05997
```

A test that can be applied to such tables is the Fisher–Yates exact test. The application in R is very straightforward:

```
fisher.test(y)¶
      Fisher's Exact Test for Count Data
data:  y
p-value = 0.05338
alternative hypothesis: two.sided
```

The test shows that the distribution is not significant: p is too large. This is interesting for two reasons: First, as can be easily seen, the p -value of the Fisher–Yates exact test of y (0.05338) is closer to the standard significance level of 0.05 than the p -value of the chi-square test of y (0.05997): The two tests differ especially with small sample sizes. Second, this is interesting since, in percentages for example, the distribution in y is of course the same as in x : *uhm:Verb* is still four times as frequent as *silence:Verb*, which shows how sensitive p -values are to sample sizes and why sample-size independent effect sizes should always be provided.

This example from quantitative corpus analysis provides only one of many uses for these two tests of correspondence between categories of nominal or categorical variables. Like many other statistical tests, the chi-square has assumptions about the data that need to be checked. Data failing to meet assumptions can be analyzed in a different way, in this case, using the Fisher–Yates exact test.

Tests

LESLIE GRANT

Tests are used in applied linguistics research to measure variables of interest to researchers. A test is “a particular type of measurement that focuses on eliciting a specific sample of performance” (Bachman, 2004, p. 9). Test tasks “elicit performance from which we can make the inferences we want to make” (p. 9). Language ability is one, but not the only, variable of interest in applied linguistics research, and therefore, language testing is a critical area of concern. Because language ability, like all constructs, cannot be seen directly, test takers demonstrate their linguistic abilities by observable choices, words, and actions. These choices, words, and actions are taken as evidence of the ability in question; thus, every test score is the result of the process of inference whereby observed performance is interpreted as indicative of the test takers’ level of ability on the construct measured. Researchers who use test scores in their own studies often count on proficiency tests that have been developed for educational purposes, but in many cases, they need to develop their own tests in order to measure the specific construct that they intend to study.

Proficiency Tests in Research

When researchers in applied linguistics include language proficiency as one of the variables in a study, it is typically operationalized, or defined for the purposes of the study, as a score from a language proficiency test. Language proficiency test scores are intended to reflect a general language ability that is independent of language training and background (Hughes, 2000). Two of the best known tests used as proficiency measures in research are the *Test of English as a Foreign Language (TOEFL)* and the *International English Language Testing System (IELTS)*. These test scores are intended for use in admissions decisions in colleges and universities. Both tests measure reading, writing, listening, and speaking by using multiple choice for reading and listening, and essays and speech samples for writing and speaking, respectively.

Research Uses of Tests

Although proficiency tests are developed for educational gatekeeping decisions, they appear frequently in applied linguistics research for varied purposes. In educational studies of language development, such tests serve as a means of describing the proficiency levels of subjects, and sometimes they are used to describe levels of outcomes that are attained by participants in the research. Second language acquisition researchers use such language test scores to operationalize levels of language ability in order to categorize learners into high- and low-proficiency groups (Gass & Selinker, 2008). In research on learners’ performance, the language samples themselves obtained from such tests are often used for study. For example, Isaacs (2008) studied speech samples from the *Test of Spoken English (TSE)* to investigate issues tied to intelligibility of international teaching assistants. Jarvis, Grant, Bilkowski, and Ferris (2003) reported on various profiles of second language writers using writing samples—including samples from the *Test of Written English (TWE)*. Finally, in language testing research, the actual tests are subjects for research studies which are

2 TESTS

typically aimed at better understanding the meaning of test scores and seeking evidence justifying their use for particular purposes.

Selecting Tests

Researchers interested in using established tests should find out if the tests have been examined in terms of psychometric characteristics such as reliability and validity. Many tests are reviewed in *Buros Mental Measurement Yearbook* (www.unl.edu/buros), and researchers can also find information at test publishers' Web sites. However, just as a critical stance is needed to examine the tasks, responses, and scoring of tests, the same is true for reported reliability and validity. Studies reporting validity should be considered in view of the sample of test takers used to conduct the validation research. Reliability, too, should be examined as it is sample specific; researchers need to estimate reliability for their own studies in addition to reporting what others have found. These explorations will lead to determining the usefulness of the test for research purposes and will lead researchers to make more informed decisions regarding their own findings when they are based, in part, on test scores.

In any research study using tests, it would be wise to try to get a copy of the test—or at least a detailed description—so that test methods and response types can be examined. In this way, the analyses and interpretations of the test scores will be more appropriate and limitations can be acknowledged in the research study. In addition, for researchers creating their own tests, examining existing tests may give them ideas.

Test Design for Research

Many researchers find that existing tests are not sufficiently focused on the specific areas of investigation in their research, and they therefore need to design their own tests. The plan, or table of specifications, is a blueprint for a test (e.g., Miller, Linn, & Gronlund, 2008). Test specifications are formulated as a basis for sampling systematically from the domain that the research needs to measure. Often a needs analysis informs the process of domain definition, so in building a listening test, for example, one might describe contexts for listening: listening at the store, listening to the gist of the news, listening for details at work, etc. In other cases, the domain is identified on the basis of the theoretical construct of interest. For example, a table of specifications for listening ability might be developed based on a theoretical definition of listening consisting of listening subskills (e.g., listening for the main idea and listening for details). Because language constructs are complex, test specifications are important for ensuring that the test will appropriately sample from the relevant domain. In order to define the relevant aspects of the test, the specifications should include information about each of the following aspects of the test method.

Input and Expected Responses

Language tests range from questions on paper to much longer performances of language use. Test takers may read prompts on a paper and write a response, role play a situation, or present a short talk on a topic. Traditional response types such as multiple choice, true/false, matching, and short answers work well for testing knowledge *about* the language, while tasks requiring learners' engagement and performance are better tests of how test takers *use* the language to accomplish certain goals and carry out tasks.

Designing appropriate methods is particularly challenging in language testing relative to other subject areas because *language is used to test language*. This challenge is even greater at lower levels of proficiency. For example, it would be futile to ask beginning language learners to produce an essay or speak for several minutes on a topic. Low-level language

learners might only be able to recognize key vocabulary and simple routine phrases. It would therefore make good sense to ask the learners to demonstrate understanding through actions, or perhaps by choosing an item from a set of choices or circling a picture of the word that is heard. Learners would need only to recognize the correct response and indicate that response.

As learners progress in language skills, the assessments frequently require the processing, production, or both of connected language or discourse. Such test tasks ask learners to work out the meaning of the language presented on the test and then produce linguistic responses, either orally or in writing, or select appropriate responses from a set of choices. Cloze tasks and information transfer tasks may be used on such tests. Listening tasks might include listening to a short conversation and answering multiple-choice questions or filling in a table or chart. Obviously, when learners are more advanced, it is possible to use tests that involve longer language segments of discourse to be either comprehended or produced. Test takers might be asked about the overall message or tone of the writer, for example. Writing and speaking samples produced by test takers are also of considerable length. For example, test takers might be asked to write or speak about influential persons in their lives or they might be asked their opinion on a topic such as animal rights.

Scores and Measurement Scales

In most tests used in applied linguistics research, test scores are typically computed as a tally of correct responses to test tasks or on the basis of judgments or descriptions of a level of test takers' performance. Selected response items are typically machine-scored. On the other hand, responses such as speech samples and essays more typically require at least one human rater who has been carefully trained. Common practice involves having two raters evaluate samples independently, using a scoring guide, or rubric, to guide their scoring. In some test settings, one of the ratings is generated by computer. Whether the raters are human or computer, inter-rater reliability, or rater consistency, needs to be maintained between the raters.

While the test scores described above are numerical, researchers should carefully consider the type of data being reported, and then determine statistical tests that are appropriate for use with that type of data. Scores computed from correct item responses are treated as interval scales of measurement; such data can be treated as continuous for statistical analyses. Ordinal data might be obtained with test scores if the scores are generated from judgments of ranked levels of language performance or if the analysis is conducted on items employing a Likert-type scale. Pass/fail or advanced/intermediate designations may represent nominal data. Other nominal or categorical data might consist of different first language backgrounds, home country, or topic assignment.

Computers and Testing

In developing tests, it is worthwhile to consider how advances in computer technology have prompted changes in tests. While some computerized tests are similar to their paper-and-pencil counterparts, other tests are uniquely created for computers with items that involve moving sentences in a language sample, using the mouse to show comprehension of geographic locations, or using technology to talk interactively online. Computer adaptive testing has also been embraced by applied linguists, and these tests result in tailored tests that can more quickly target a learner's ability in many cases.

With these advances, research directions related to technology and its impact on language testing have been pursued. Examples include work on the length of reading passages delivered on the computer (Liu, Schedl, Malloy, & Kong, 2009), investigation of visuals in computer-based testing (Ginther, 2002; Ockey, 2007), and computer familiarity (Taylor,

Kirsch, & Jamieson, 1999). Chapelle and Douglas (2006) provide an informative discussion of advances in computer technology in testing, suggesting that it may be possible to test in new and different ways through the use of technology.

Conclusion

Tests are an important part of research in applied linguistics. Researchers should note, however, that test scores do not equal *true* language ability. Linguists continue to debate the construct itself, while language testers do their best to create procedures that will enable language learners to demonstrate what they know or can do with language. To complicate matters further, tests are not administered in a vacuum to only one type of learner; thus, factors such as test administration, conditions, format, method, scoring, and the test takers themselves introduce variation or “noise” in a way that makes it challenging to be sure that a test score does, in fact, represent language ability. Likewise, individual factors such as background knowledge, prior experience, and test anxiety can influence test performance. Research on working memory indicates that test takers vary in their ability to remember cognitively demanding information. In a listening test, for example, often a stimulus is only heard a single time, making it critical for the examinee to remember what he or she heard. Thus, individual variation in working memory adds an important layer to test performance, and test scores are impacted. Research in these areas and others tied to learners continues to inform testing practices and test score interpretation. Researchers who are informed about these issues will be better able to understand the strengths and shortcomings of the tests they use.

Text-Based Approaches to Translation

LEONARDO GIANNOSSA

Theoretical Tenets

The text-based or textual approach to translation regards a text as a communicative act which takes places in a situationally and culturally significant context. In this sense, translation is more than a mere interlinguistic transcoding activity. The text to be translated, or, as is often referred to by translation scholars and translators, the source text (ST), is viewed as a coherent chunk of lexical items and is analyzed globally at the supra-sentential level by looking at its overall meaning, textual features, and communicative function(s). The translation unit is no longer the word or sentence, as is the case with the linguistic approach, but rather the text as a whole. The translator's task is to produce a translation or target text (TT) which is textually and communicatively equivalent to the ST. This is accomplished by encoding the ST information into equivalent target culture textual prototypes (see Neubert & Shreve, 1992, discussed below).

To better understand how this approach deals with the translation process, it is first necessary to talk about text linguistics, a discipline which emerged in the 1970s and informed many of the theoretical constructs and notions underlying the textual approach to translation. The theoretical foundations of text linguistics can be traced back to the late 1960s when linguistic researchers felt the need to investigate language beyond the sentence level. This need was met by the emergence of such fields as *discourse analysis*, *text grammar*, and *pragmatics*.

Within text grammar, a new theory of text which shifted the focus of analysis from the micro- to the macro-level was put forward by Petöfi (1971) and van Dijk (1972). Petöfi, on the one hand, added a new dimension to the study of texts which had until then been disregarded, namely *contextuality*, which refers to nontextual relations such as text reception and text interpretation. Van Dijk, on the other, described texts as consisting of a deep or macrostructure and a surface or microstructure.

Another important turn in linguistics, which also contributed to the shift from the sentence to the textual level, was the so-called *pragmatic turn*, which was initiated by Austin (1962) and his *speech act theory*, and by Grice (1975) and his *maxims*. They both focus on the implicit force of utterances and point out that the interpretation of them may depend on the pragmatic occasions on which such utterances occur.

It is de Beaugrande and Dressler (1981), however, who bring together the syntactic, semantic, and pragmatic features in the description of texts. In their pioneering work *Introduction to Text Linguistics*, they define a text as "a communicative occurrence which meets seven standards of TEXTUALITY" (p. 3). These seven standards are: (a) cohesion, (b) coherence, (c) causality, (d) intentionality, (e) acceptability, (f) informativity, and (g) intertextuality. The authors state that whenever any of these seven standards fails to be achieved, the result is a noncommunicative text, that is to say, a nontext. Besides, this idea of texts as communicative occurrences points to the purposefulness of the communicative act in which the text takes shape and meaning. In other words, a text is produced to fulfill a communicative function, which is one of the main concepts on which the textual approach is grounded.

The introduction of text linguistics into translation studies also questioned the word- and sentence-level notion of equivalence which until the 1970s was advocated by many exponents of the linguistic approach to translation. As a matter of fact, it is only after text linguistics found its application to translation studies and translation began to be viewed as representative of a particular text type that the notion of equivalence acquired a textual/global meaning (Luo, 1999).

Eugene Nida may in this respect be regarded as one of the precursors of the global approach to text analysis and translating. His notion of equivalence in translation could be said to anticipate what would later be known as the textual approach. He views the act of translation as a reproduction in the target language (TL) of "the closest natural equivalent of the source-language message, first in terms of meaning and secondly in terms of style" (Nida & Tabber, 1969, p. 152). Nida also states that "the traditional focus of attention in translation was on the word. It was recognized that that was not a sufficiently large unit, and therefore the focus shifted to the sentence. But again, expert translators and linguists have been able to demonstrate that individual sentences, in turn, are not enough. The focus should be on the paragraph, and to some extent on the total discourse" (p. 152). Though Nida never applied text linguistics to translation, he held the view that translation units extended beyond the sentence.

The common belief shared by linguistics-oriented and linguistics-informed translation scholars, that translation occurred between the words of two languages, was challenged, as Neubert (1996) points out in his article "Text-Linguistics of Translation: The Textual Approach to Translation," by "the advent of text or discourse analysis in the 1970s and 1980s" (pp. 87–8). Thanks to the discourse perspective, the author adds, the notion of translation unit widened and so did the translator's horizon. Translators started looking beyond the individual words and phrases, thus taking into account what happens at the inter- and supra-sentential levels. Neubert claims that, with the advent of the textual perspective on translation, the focus shifted from "a more narrow semantic to a wider communicative or semiotic perspective" (p. 90). The textual approach is in Neubert's view grounded on two tenets, or rather, there are two aspects to it, which are termed *holistic translation* and *generic translation*. These two aspects, put together, make up the so-called textual approach.

The holistic approach claims that the general purpose of translation is to capture the overall message of the ST and transfer it into the TT. Both the translation process and product are ultimately justified on the basis of any assessment of the global textual function. With the exception of intertextuality, the standards of textuality need to be reproduced and respected during the translating act. However, it is pointed out that since these standards are culture-specific, they depend on what constitutes normal reading in the target culture and for the target readership. The generic approach to translation, on the other hand, involves "paying attention to grammatical, lexical, and stylistic markers characteristic of an entire class of texts forming a part of a text world" (Neubert, 1996, p. 94). Translating a text implies translating a member of a particular text type or genre with all its distinctive features characteristic of that particular class of texts. It is emphasized that it is the concept of text type that underlies the notion of generic translation. Many text linguists and translationologists have over the years tried to come up with their own text typologies based on communicative functions (Buhler, Reiss, etc.). However, Neubert (1966) notes that these classifications are subjective and that, rather than focusing on devising a universal system of features characterizing specific text types, researchers should focus on compiling a list of features that a group or groups of texts share. In other words, they should concentrate on the intertextual relationship.

Another core idea underlying the textual approach to translation is the notion of *communicative value*, which replaces the linguistics-based notion of meaning. Indeed, as stated

in Neubert's article and later on in his book co-written with Gregory Shreve (1992), translators deal with communicative value. Unlike meanings, which are components of the linguistic system, communicative values are derived holistically from their position in the entire text and generically from the role they play in shaping a specific text type (Neubert, 1996).

Text-Based Models

Over the past forty or so years, a number of translation scholars have put forward several text-based translation models. All of them are characterized by a top-down approach to text, analysis and text-type classification. As a rule, their classification of texts, in general, and translations, in particular, is based on language and textual functions. Of all the language models that have been proposed over the years, three have mostly been used in and applied to the translation field: Bühler's (1990/1934), Jakobson's (1960), and Halliday's (1970).

German psychologist Karl Bühler, in his threefold organon model of language, distinguishes between representational, emotive-expressive, and conative functions (1990/1934, pp. 34–7). Representational function is related to objects and relations in the real world and describes extralinguistic reality; emotive-expressive function is associated with the speaker/writer of the message; and the conative message is focused on the receiver of the message.

Jakobson (1960) adopts Bühler's distinction but adds three more functions based on his communicative act model: phatic, metalingual, and poetic functions. The phatic function is contact-oriented and is used to establish, prolong, or discontinue communication. The metalingual function is focused on the code, whereas the poetic function is focused on the message.

Halliday (1970), by contrast, proposes a simple categorization of language functions. He identifies only three of them: ideational, interpersonal, and textual. His ideational function is content-oriented; his interpersonal function expresses a speaker's attitudes and also aims at influencing the addressee's behavior. His textual function is what links language with the situation in which it is used. This textual function relates to the internal organization of linguistic terms. Since a text is language in use, it inevitably implies the first two functions, ideational and interpersonal, which may be regarded as the two components of the textual function.

As far as translation theory is concerned, Katherine Reiss (2000/1981) applies Bühler's language functions to translation through her text-bound approach. She states that in order for translators to produce a functionally equivalent TL text, they need to find out the functions of the source language (SL) text. As a matter of fact, Reiss, as one of the prominent proponent of the functionalist approach, defines texts as *intentional* (my emphasis) acts of communication. By "intention," the author refers to speech purpose, the verbalization of which endows a text with one or more communicative functions of which only one is dominant. She proposes a three-stage process for clarifying the functions of the SL text.

The first stage of the analysis aims at the establishment of the text type, though she points out that this kind of ST-based text typology is valid as long as the function of the translation is the same as that of the original document. She identifies three basic text types: informative (focus on the content), expressive (focus on the artistic organization of the content), and operative (focus on making the content persuasive). This text-type classification is solely based on Bühler's functions of the linguistic signs (representational, emotive-expressive, and conative functions), rejecting Jakobson's phatic and rhetoric functions on the grounds that they do not actually give rise to a specific text type but are rather

realized in one of the three forms of communication identified by Reiss (namely informative, expressive, and operative). In addition to these three basic types, she isolates one more: the multimodal text type, which relates to material consisting of verbal texts accompanied by additional nonverbal information.

The second stage of the analysis aims at the establishment of the text variety, which is defined by the author as “super-individual acts of speech or writing, which are linked to recurrent actions of communications and in which particular patterns of language and structure have developed because of their recurrence in similar communicative constellations” (Reiss, 2000/1981, p. 165). The third and last stage is the analysis of style. At this stage, the translator has to identify which linguistic means were used by the author to realize specific communicative functions, as well as clarify how the text is constructed.

After this three-stage analysis comes the reverbalization phase, whereby the ST content is transferred into the TT. In the reverbalization phase, the text type determines the general method of translation, whereas the text variety determines the choices that the translator has to make as to language and text structure conventions.

Like Reiss’s, Nord’s model of text functions draws on Bühler’s language model, but adds a fourth, which she calls phatic function. Nord (2005/1988) too adopts a functionalist approach to translation and proposes an analysis of the ST as a benchmark for decisions about the feasibility of the translation task, which ST units will be relevant to a functional translation, and which translation strategy to adopt. Unlike Reiss, however, Nord considers the TT purpose, as described in the initiator’s instructions, as the main determinant of a translation. Though the TT function is the one determining the translation process, the translator still needs to undertake an ST analysis, because only by comparing the function of the ST with that established by the initiator can one decide which ST elements to keep or change during the interlinguistic transfer. According to Nord’s model, the text is taken to be a communicative interaction, since it is used or produced within the framework of a communicative situation involving a sender, a receiver, a message, a code or medium, and a purpose which justifies the communicative act. Her distinction between text and nontext is grounded on the criterion of communicative function, which is the main determinant of textuality in a text. Indeed, the syntactic and semantic features of a text are subordinate to the communicative function thereof.

Nord’s text approach to translation is top-down, starting from the pragmatic level. At this level, the translator has to decide the function of the translation, and a distinction has to be drawn between the functions that will be kept invariant in the TT and the ones that will be adapted. The second level concerns the conventions, more precisely style conventions, which will be determined by the translation type chosen on the basis of the function. Only after these two stages will the differences in language come into play.

A major contribution to the textual approach to translation came from Neubert and Shreve (1992), who thoroughly describe the textual approach in their work *Translation as Text*, in which they state that, in the top-down approach characterizing the text-linguistic model, sentences are translated by taking into account the conventions existing for a particular text type or textual category in a particular culture. This model locates meaning equivalence beyond the sentence level, namely at the textual and communicative level. The two authors identify seven factors accounting for the creation of textual and communicative equivalence. These factors are: (a) intentionality, whereby a text is written to attain a particular goal (the author’s intent); (b) acceptability, which means that the text needs to be accepted as such based on peculiar textual features; (c) situationality, which implies that a text is always situated in communicative and social settings; (d) informativity, which is “a measure of the information a translation provides to an L2 [second language] reader about L1 [first language] events, states, process, objects, individuals, places and institutions”

(p. 89); (e) coherence, which refers to the logical structure existing between informational units in a text; (f) cohesion, which is “the reflection of semantic coherence at the textual surface” (p. 102); and (g) intertextuality, which relates to the set of expectations about what a text should look or be like. Neubert and Shreve (1992) also maintain that textual equivalence derives from prototypes, which are defined as “knowledge structures which are used and applied when interpreting or producing a text” (p. 130). It follows that two texts are said to be equivalent when “their textual profiles are derived from situationally and functionally equivalent prototypes” (p. 142). Hence, in order for the ST and TT to be communicatively equivalent, they do not need to share the same textual surfaces or semantic content, but rather need to “yield similar information to similar readers in essentially similar situations” (p. 143). Therefore, it is the function and purpose of a translation that are decisive factors in producing and assessing communicative equivalence.

Snell-Hornby (1995/1988), in *Translation Studies: An Integrated Approach*, deems translation to be a matter of texts culturally embedded in situations. Her integrated approach was, as she points out, influenced by the Gestalt school, in particular by the principle which states that the whole is more than the mere sum of its parts. Applied to translation, this means that the analysis of the parts “cannot provide an understanding of the whole” (p. 35). Her approach provides for a text analysis proceeding from the macrostructure of the text to the micro-unit of the sign. The first step that the translator has to take is to see the ST as a unit embedded in a given situation. The text is to be identified in terms of culture and situation. The second step is to analyze the structure of the text by tracing the web of relationships among lexical items. The third step involves using Fillmore’s (1977) scenes-and-frames approach, according to which the linguistic forms used in a text are always related to the experience and response of a reader. Frames are collections of words and grammar rules whereas scenes are the experience situations that find expression in frames. Applied to the translation process, this implies that the translator-reader builds up scenes from the SL frames, and these scenes are affected by the translator’s experience and internalized knowledge. Then she or he has to choose TL frames that are able to evoke those very same scenes in the TT (Snell-Hornby, 1995/1988).

Last but not least, Juliane House’s (1981) textual approach, though mainly developed for quality assessment, provides a detailed model for the ST and SL function analysis which Reiss’s (2000/1981) model vaguely accomplished. In House’s view, equivalence implies preserving three aspects of meaning across two different languages: semantic, pragmatic, and textual. Of the three, it is the textual meaning that should be kept invariant in translation since it links sentences into a cohesive and coherent whole. In House’s words, a textual function is “the application or use which the text has in the particular context of situation” (1997, p. 37). To identify this function, she relies on register analysis, in that register correlates linguistic features with situational features. The author later proposed a revised model which features genre as a linkage category between register and textual functions, because she realized that some of the deeper similarities and differences between texts cannot be accounted for by such situational dimensions as tenor, field, and mode of discourse (House, 1997).

Overall, the above-mentioned text-based models could be grouped into two major approaches. One is purely text-linguistics-driven and resorts to register, discourse, and pragmatic analysis to find out about the syntactic, semantic, stylistic, and pragmatic regularities of the ST so as to produce a situationally and linguistically appropriate TT. Within this approach, Nord, House, and Snell-Hornby stand out. The other approach may be labeled text classificatory in that text type is the major determinant of translation strategies and the benchmark for translation quality assessment. Reiss’s and Hatim and Mason’s (1990) text classifications exemplify this approach to translation.

Text-to-Speech Synthesis Development

CAROLINE HENTON

Background

Speech synthesis, as defined in *The International Encyclopaedia of Linguistics*, “is the automatic generation of speech using linguistically salient acoustic or articulatory properties, or spoken units that are selected and controlled using computational commands” (Clark & Henton, 2003). Machines that synthesized speech (synthesizers) were unveiled first in 1939 at the New York World’s Fair. In the following 50 years, early vocoder synthesis was improved upon by parametric synthesis and linear predictive coefficient (LPC) synthesis. Parametric (or formant) synthesizers get control information either by analyzing relevant acoustic parameters in speech, or by rules operating on a character string (i.e., text). LPC synthesis uses the representation of the speech signal as a set of coefficients that try to predict the signal from past values in the time domain; LPC accounts for resonance and pitch movements well, but fails in natural voice quality because of the invariant nature of glottal pulses. For a history of the development of, and progress in, speech synthesis, see Klatt (1987), van Santen, Sproat, Olive, and Hirschberg (1997), and Clark and Henton (2003).

The speech quality of vocoder, parametric, and LPC synthesizers, while useful in speech perception and modeling research, was not acceptable for wide, mainstream deployment in commercial applications until the early 1990s. At that time, synthetic speech research and development switched to the concatenative method whereby units recorded by a human being (diphones, syllables, words, phrases, and so forth) are selected from a large database according to sophisticated algorithms, to be spliced together to form new utterances. The widespread use of the variable-length unit selection approach (Henton, 2002a) has brought much improved naturalness and intelligibility to synthetic speech.

Text-to-speech (TTS) systems transform text and symbols into spoken output. TTS systems are the most widely used application of speech synthesis in, for example, information technology and aids for the blind and people with other disabilities. Typical TTS systems contain modules for text normalization (illustrated below), morphological analysis and parsing, lexicon(s), grapheme-to-phoneme rules, and phonological rules.

This entry focuses on the development and deployment of general-purpose, unrestricted TTS synthesis in the most common scenarios for American English. It does not survey Web-based, free, embedded, or niche TTS that has been designed or modified for use in, for example, mobile devices (smartphones), navigation systems, “talking dictionaries,” hand-held speaking translators, or other limited language-learning applications, including simple “speak and spell” applications.

High-Quality TTS Synthesis Across Languages

Currently, the most natural synthetic speech available in American English is “Alex,” a male voice integrated with the Mac OS X operating system on all Apple computers. This voice is scalable: It can handle a large increase in users or workload without undue strain. It is used to speak music titles and artists on iPod devices, as well as forming the core of

the “VoiceOver” application (see below). High-quality American English TTS that runs under the Windows operating system and others is also available from AT&T (www.research.att.com) and Nuance Communications (www.nuance.com). Over the course of two decades, Nuance has come to dominate the American English speech technology market by merging with or acquiring other TTS providers, including Lernout and Hauspie, Berkeley Speech Technologies, Centigram Communications, Dragon Systems, Rhetorical Systems, and SpeechWorks. Nuance now supplies two TTS systems: RealSpeak™ and Vocalizer 5. The synthetic speech produced by Tellme (www.tellme.com) is unique because it is designed to speak items in niche data domains. When combined with mobile GPS and Microsoft’s Bing search engine, Tellme’s voice services allow spoken query and TTS response for stocks, sports, news, weather, and driving directions, for example. However, if Tellme’s “Zira” synthetic voice is used for general text output, unnatural segmental errors are apparent, and prosody is absent except for declarative statements.

Scottish-based Cereproc (www.cereproc.com) has developed diverse voices with American, Scottish, Black Country (loosely, Birmingham, England) and Southern British English accents. The European Acapela Group (www.acapela.com) has TTS in 25 languages that use 50 standard voices or a user’s own voice. More than 20 of Acapela’s Infovox (small footprint) voices are integrated for personal accessibility use by AssistiveWare, based in the Netherlands. Loquendo (www.loquendo.com) offers TTS for all major European languages, Australian English, some “minority” languages such as Catalan, Valencian, and Galician, and a broad variety of Latin American Spanish dialects: American, Argentinean, Chilean, and Mexican. Romanian-based Ivona (www.ivona.com) produces TTS in Romanian, Polish, American English, and two British English voices developed in cooperation with the Royal National Institute of Blind People (RNIB), UK. In addition to American English, NeoSpeech (www.neospeech.com) provides TTS in Japanese, Mandarin Chinese, Korean, and Latin American Spanish.

TTS Applications for Blind, Deaf, and Physically Challenged People

People who depend on speech synthesis include the blind, the physically impaired, those suffering from repetitive stress injuries (RSI), dyslexics, autistic children, and others who have language impairments (Henton, 2002b). For these individuals, TTS is used in quotidian tasks that involve audio feedback; for example, to verify the computer has heard them correctly, to read aloud information, in delivering instruction, practice exercises, encouragement, and confirmation messages. Speech synthesis may also be used for speech input to computers or other “listening” devices.

People who are blind or have low vision are served especially well by Apple Computer. Every new Mac computer includes an advanced, full-featured screen-access technology, called VoiceOver, that allows control of the computer. VoiceOver (www.apple.com/accessibility/voiceover) offers much more than simple TTS. It uses speech to describe the status of the computer and actions and activities as they occur. It also provides additional keyboard commands and other input options, including Braille display input. VoiceOver is unique because, unlike other speech tools and aids for the visual- and learning-disabled (e.g., Kurzweil 3000, www.kesi.com/research.aspx), it is not a stand-alone screen reader: It is integrated into the Mac OS X operating system. VoiceOver works with a wide range of applications—word processors, spreadsheets, browsers, audio software, utilities, and more, including those built into Mac OS X. VoiceOver is also the first screen reader to provide plug-and-play support for Braille displays.

In 2009 Animated Speech Corporation (<http://itunes.apple.com/us/artist/animated-speech-corporation/id340888074>) released an animated tutor iPhone application that uses

Baldi®, a “talking head” (agent) created by Massaro and colleagues (Massaro, 2006). Baldi provides realistic visible speech and can read aloud Web pages, RSS feeds, books, articles, and personal text files. Users control the rate of speaking, facial look, and emotion. No Internet connection is necessary for the speech and animation, because the software runs locally on the iPhone platform.

Talking Agents, Language Tutoring, and the Needs of Hearing-Impaired People

Talking agents can provide visual speech cues to make messages more understandable for the hearing impaired, as well as for others in difficult environments, like parties and crowds. Talking agents are autonomous software agents that communicate using speech and (facial) gestures to behave like interactive partners, and to supply relevant information. Using visible speech and any TTS system such agents can supply effective language tutoring. Talking agents are popular with children: Deaf-oral children, autistic children, students of English as a second or foreign language, reading-disabled (including dyslexics), and first language learners may all benefit from such visible speech.

There are many advantages to using talking agents such as Baldi as language tutors (Massaro, Cohen, Beskow, & Cole, 2000). Agents never get tired, bored, or impatient; they never suffer from sore throats; or have “bad days.” Massaro, Cohen, Beskow, and Cole (2000) used the “Vocabulary Wizard” in schools for profoundly deaf-oral children, where pupils wear hearing-aids, have cochlear implants, or a combination of both, to enhance their hearing. These children improved their speech perception and production, and increased their vocabulary (Massaro, 2006). Using synthetic speech in language tutoring allows for endless repetition and volume adjustment to suit the user. More importantly, some training manipulations for deaf-oral children are easier to do with synthetic speech, such as lengthening the speech segments. Additionally, Baldi has a transparent mouth model, showing the tongue, palate, teeth, and lips. The tongue can be controlled to mimic natural tongue movements (Massaro, 2006). Tongue movements can be slowed down to emphasize place of articulation, and the rate of the synthetic speech can be reduced to rates far slower than a human could produce. Using a see-through dynamically talking agent, critical speech organs can be highlighted, noncritical parts can be hidden, and normally hidden parts can be revealed. Further, the orientation of the face can be changed to display different viewpoints while speaking, such as a side view, or a view from the back of the head (Massaro, 2006). All these features are of great benefit to deaf-oral and autistic children, who have difficulty in perceiving auditory speech alone. Teachers and parents believe that this learning is better than if the children had received human instruction alone.

Autistic children are most commonly diagnosed by a limited ability to comprehend and produce spoken language. They also exhibit cognitive, perceptual, and social differences. About 50% of autistic children fail to develop any form of functional language (Massaro, 2006). Moreover, many who do eventually speak exhibit language development delay. Any tools that can assist these children with developing communication skills are valuable. Students with autism have learned a significant proportion of new words using a vocabulary-training program. These children react well to synthetic communication; indeed, it appears that computer lessons are intrinsically motivating for most autistic children. Computers diminish the difficulties (and distractions) autistic children experience in face-to-face social interaction. Of course, there is always the danger that learners will mispronounce a word if the TTS mispronounces it.

Talking agents can provide phoneme-discrimination exercises, storybook reading, and constant vocal companionship, and, in an extreme case, they can be thought of as virtual

caregivers. Developmentally dyslexic children may improve their phonological and reading skills using an agent as a tutor. Talking agents can highlight and pronounce troublesome spelling sequences and different parts of a sentence, and add paradigms of similar-looking or similar-sounding words.

Synthetic Speech for Narration

Using synthetic speech for narration is more efficient and cost-effective than a human reading; there is no need to record hours of text, and the content can be updated easily. Electronic reader-devices can read aloud books, newspapers, and RSS feeds without the need for the author or a voice talent to read the text. For these applications, it is essential that the TTS includes excellent *text normalization*. Text normalization transforms text to make it consistent; it is performed before text is processed to generate synthesized speech. Such processing includes correct interpretation of lower or upper case letters (including acronyms), removing punctuation and diacritics from letters, and expanding abbreviations.

The TTS provider must also monitor pronunciation accuracy frequently, to avoid such embarrassment as the mispronunciation of “Obama” and “Celtics” by Nuance’s TTS on the Kindle 2. Woo (2009) and colleagues have designed enhanced podcast content for iPods with color screens, which also contain archival images and maps. There are plans to narrate tours (of, e.g., Sydney’s Birthplace Walk) using synthetic speech.

Emotions in TTS

The development of both stylistically and emotionally expressive synthetic speech has been investigated for many years (Henton & Edelman, 1996). The overall conclusion from speech research, language modeling, and psychology is that it is impossible to find invariant acoustic speech patterns with recognized emotions. Nevertheless, Loquendo has marketed expressive synthetic speech. Their voices have been enlivened with a repertoire of “expressive cues.” The inclusion of this feature appears to have compromised both the naturalness and the accuracy achieved through unit selection.

Variety in Synthetic Speech

Early speech synthesizers produced only male voices well (Henton, 1999). This presented a real problem: In 1982, a young woman suffering from cerebral palsy noted that she used a mechanical voice to speak but found it demoralizing that only a male voice was available to her. In addition to being ignored, women’s voices were often lumped together with those of children. As late as 1987, Klatt lamented, “it is very likely that a synthetic female voice will remain an elusive goal” (Klatt, 1987, p. 781). Developments in concatenative synthetic speech in the 1990s allowed researchers to synthesize female speech better. In the past two decades, synthetic voices have become more diverse and represent voices across sexes and more ethnicities and cultures. Speech databases exist for the creation of synthetic speech with different English accents, such as British, American, and Australian (see above), Welsh (Williams, 1995), and Indian (Sen & Samudravijaya, 2002). However, no synthetic speech exists, for example, in Jamaican or South African English. The lack of African American synthetic voices raises a question about equal access for all across the United States.

Conclusion

Synthetic speech is available in many languages and deployed in a wide range of environments. Benefits of this technology have spread into education, factory assembly lines, navigation systems, and entertainment, as well as providing essential assistance for physically, visually, vocally, and hearing-impaired people. Some potential applications for TTS, for example in reading prescriptions and drug names, should not be pursued for safety reasons (Henton, 2005). Predictions that it will soon be possible to synthesize any kind of text in a specific style (e.g., emphatic, formal, informal, and so forth) and in the emotional tone required (e.g., happy, sad, angry, and so forth) are premature. It remains important to continue to test TTS performance in the areas of pronunciation accuracy, text normalization, pausing, and other aspects of prosody. General-purpose TTS systems will continue to improve with better rules for intonation and (de-)accenting, with the semantic disambiguation of homographs, and with the constant maintenance of exceptions dictionaries. It may yet be possible to dispute van Santen's claim (1998) that TTS systems require real-world knowledge to sound perfectly natural.

Text-to-Speech Synthesis in Computer-Assisted Language Learning

ZÖE HANDLEY

In very simple terms, speech synthesis is the process of making the computer talk, and text-to-speech (TTS) synthesis is a specific type which takes raw text as input and aims to mimic the human process of reading. TTS is the technology which allows dictation software, such as IBM ViaVoice, to *read* your dictated texts back to you. It was also the technology behind Texas Instruments' Speak & Spell spelling bee program launched in the 1980s. While interest in the use of TTS in computer-assisted language learning (CALL) only really began to take hold around the year 2000, some of the potential benefits of the use of TTS in CALL had already been identified around the time that Speak & Spell was launched. At this time, Bruce Sherwood (1981) observed that typing/editing text is easier than (re)recording voice, that navigating through a textual database is easier than retrieving recorded samples from an audiotape, and that TTS synthesis has the capacity to generate speech models on demand—benefits which researchers continue to see in the use of TTS synthesis in CALL (Dutoit, 1997; Keller and Zellner-Keller, 2000; Handley and Hamel, 2005; Kang, Kashiwagi, Treviranus, & Kaburagi, 2008). This entry discusses the way in which these benefits have been exploited to provide learners with tools to support them in their language-learning activities as well as tutorial software focusing on the acquisition of specific areas of linguistic knowledge and language skills.

Tools Integrating TTS Synthesis

Two classes of tools have been developed to support students in their language-learning activities which exploit the benefits of TTS synthesis presented above. These are “talking dictionaries” and “talking texts.”

Talking Dictionaries

Talking dictionaries are electronic dictionaries which integrate audio for the presentation of the contents of dictionary entries. The integration of audio to convey the pronunciation of the words is particularly useful for learners because it bypasses the need to be proficient in interpreting phonetic transcriptions, something which can be very difficult given conventions vary (Knowles, 1986). Talking dictionaries integrating digital recordings of human speakers also bypass this need. However, dictionaries integrating recordings of human speakers typically only provide one pronunciation model per entry, that of the headword. The generative power of TTS makes it possible to provide learners with pronunciation models for not only the headwords, but also their inflectional forms, derivations, synonyms, and antonyms as well as definitions and examples of usage. Few talking dictionaries, however, exploit this unique capacity of TTS synthesis. Two examples which do are the Breton talking dictionary produced by Mercier et al. (2000) and the *Oxford Hachette French Dictionary on CD-ROM*. Yachi's (2007) talking dictionary for young learners of English exploits the capacity to generate speech models on demand in a different way. This dictionary, which is compatible with interactive whiteboards, is authorable.

Talking Texts

The *Oxford Hachette French Dictionary on CD-ROM* also integrates a talking-text facility, a tool which will read aloud any section of text the learner types or copies into it from another application. Talking texts are also quite popular in CALL. Another example of a talking-text facility can be found in *Spanish for Business Professionals* by Kirk Hagen of the University of Houston Downtown. Each unit of this course focuses on a dialogue. Having studied this dialogue, learners are encouraged to practice the language they have acquired in a chatroom. Learners can use the talking-text facility to listen to their own and others' messages.

Dictation systems, such as IBM ViaVoice and Dragon Naturally Speaking, are an extension of talking-text applications. Dictation systems integrate both automatic speech recognition (ASR) and TTS to allow the user to dictate a text and have that text read back to them. As extensions of talking-text applications, one can imagine dictation systems also being used in language learning as described above (Chapelle & Jamieson, 2008). The same is true of screen readers. A screen reader is a piece of software designed for use by the visually impaired and people with language impairments, which reads aloud the contents of the computer screen using a TTS system. Some commercially available examples are TextHelp, NaturalReader and ReadPlease.

Tutorial Software Integrating TTS Synthesis

As mentioned above, it has also been suggested that tutorial CALL could exploit the benefits of TTS.

Vocabulary

There are two specific benefits of using TTS in tutorial software focusing on vocabulary. First, TTS enables learners to access the pronunciation of a word in addition to its form and meaning. As Nation (2001) observes, there is more to knowing a word than being able to recognize its orthographic form and retrieve its meaning. Second, as mentioned above in relation to talking dictionaries, using TTS for the presentation of pronunciations bypasses the difficulties associated with phonetic transcriptions (Knowles, 1986). The *Software Linguistico Interattivo Multimediale* (SLIM or *System for Interactive Multimedia Language Learning*; Delmonte, 2008) is an example of a piece of tutorial CALL software focusing on vocabulary which exploits these benefits.

Grammar

The advantages of using TTS in tutorial CALL focusing on grammar are similar to those of using it in vocabulary CALL (Handley, 2006) and have been exploited in a variety of ways. TTS has been used to aurally present grammar exercises from the learners' normal course-book in a language laboratory setting (Stratil, Burkhardt, Jarratt, & Yandle, 1987; Stratil, Weston, & Burkhardt, 1987), text unscrambling exercises (Delmonte, 2008), and automatically generated individualized grammar exercises (de Pijper, 1997). The latter use is particularly interesting because it takes full advantage of the generative capacity of TTS to provide learners with unlimited practice with aural support.

Pronunciation

In contrast with the use of TTS in vocabulary and grammar software, the use of TTS in tutorial CALL focusing on pronunciation is controversial. While some argue that "the current quality of synthesis varies from language to language and [is] not fully ready as

a model for students who are learning to speak like the natives” (Egan & La Rocca, 2000, p. 5), others believe that TTS may be particularly suitable for use in the teaching of pronunciation, in particular intonation: “The advantage of synthesized intonation contours compared to those realized by the speaker is that their melodic pattern is more formalized. Thus the generalized contours free from additional emotional coloring are used as models” (Skrelin and Volskaya, 1998, p. 24). Nevertheless, a few tutorial CALL systems focusing on pronunciation have been developed. SAFexo, a module of the *Système d’Apprentissage du FRANçais* (SAFRAN) CALL environment (Hamel, 2003), uses TTS to provide the pronunciation models in exercises focusing on both the phonetic and prosodic levels. Software for learners of Breton produced by Mercier et al. (2000) uses TTS to provide pronunciation models at the prosodic level.

Reading

A very general benefit of the use of TTS in tutorial CALL focusing on reading might be that it helps learners to focus on what they are reading and stops them becoming overwhelmed by the multiplicity of links and colors characteristic of Web-based materials (Moisa & Ontanu, 1999). More specifically, tutorial CALL applications have been developed to support the development of both lower-order and higher-order reading skills. In terms of lower-order skills, the ability to match letters, or graphemes, to the speech sounds that they represent is believed by many to be a prerequisite for reading. In response to this, the CALL tutor SAFRAN (Hamel, 2003) integrates TTS to provide learners with a model against which they can compare their productions in three activities designed to reinforce the grapheme-to-phoneme, namely (a) anagrams, (b) tongue twisters, and (c) karaoke. Regarding higher-order reading skills, the SLIM system (Delmonte, 2008) integrates TTS for the presentation of reading comprehension activities. The comprehension questions are automatically generated by the natural language generation system GETARUNS; Delmonte’s SLIM system, therefore, also exploits the capacity of TTS to automatically generate speech models on demand.

Writing

TTS has also been used in exercises designed to reinforce the phoneme-to-grapheme relationship. For example, in the CALL system SAFRAN (Hamel, 2003), TTS provides the stimuli in the following activities: (a) gap-filling (or cloze) exercises, (b) hangman, (c) word searches, (d) homophone exercises, and (e) dictations. Of these, dictation is quite a popular use of TTS and its benefits have been exploited in a number of different ways. While SAFRAN does not take advantage of the unique capacities of TTS which include its ability to generate models on demand and its flexibility—SAFRAN uses TTS to read pre-determined texts to the learner—Sherwood’s (1981) software for Esperanto exploits the capacity of TTS to generate speech models on demand to provide learners with individualized feedback, and Ordictée, the Breton dictation system developed by Mercier et al. (2000), exploits the flexibility of TTS synthesis to dynamically adapt the speed of delivery of dictations to learners’ pace (typing speed). In terms of higher-order writing skills, it has been suggested that aural feedback provided through the use of TTS synthesis might help learners to notice errors in their written compositions (Chapelle & Jamieson, 2008).

Speaking

Arguably, the best way to develop speaking skills is through conversational interaction with native speakers. While computer-mediated communication (CMC) technologies such as chat applications and Skype have made it easier for learners to get such conversational practice, many learners may be daunted by the prospect of engaging with a native speaker.

Computer-simulated conversational practice with an avatar may help learners to build their confidence. There are, however, a number of obstacles to providing this sort of practice. One is that responses in dialogues are unpredictable and may be infinite in number. It is therefore not possible to predict and store all possible responses to learner utterances using digitally recorded human speech. TTS synthesis with its unique ability to generate spoken utterances from text on demand provides part of the solution to this problem—speech understanding and dialogue management systems provide the others (Jurafsky & Martin, 2000). Spoken Conversational Interaction for Language Learning (SCILL; Seneff Wang, & Zhand, 2004) is an example of a CALL system that integrates TTS for this purpose.

Listening

Traditionally, listening was taught by presenting learners with a passage to listen to and then asking them to answer questions and complete activities based on that passage. TTS is being used to present activities of this type in software developed by the Virtual Language Center (VLC), namely Storyboard, Cloze and Jumbler games. While many attempt to teach listening in this way, for others this is not *teaching* listening, it is *testing* listening. In this vein, TTS has been integrated into activities aimed at teaching low-level listening skills. For example, Sherwood's (1981) CALL software for Esperanto also uses TTS to present the stimuli in auditory discrimination exercises, as does SAFRAN (Hamel, 2003).

Is TTS Ready for Use in CALL?

Despite the potential benefits of the use of TTS in CALL, as we have seen above, few applications have been commercialized. One potential reason for this is that many still associate TTS with the robotic speech produced by early TTS systems such as that used in Speak & Spell. Yet, the quality of the output of TTS systems has significantly improved since the 1980s. In fact, some believe that the quality of TTS has improved to such an extent that the output for short utterances is indistinguishable from recordings of human speech and might, therefore, pass the Turing Test (Schroeter et al., 2002). The output of TTS systems is, however, still not free from error and does not sound perfectly natural. In fact, perfectly natural-sounding speech may remain elusive for many years to come because TTS systems require real-world knowledge to resolve some of the ambiguities found in texts and determine appropriate prosody (van Santen, 1998). The question remains whether the quality attained by current TTS systems is adequate for use in CALL. On this point, while some argue that anything less than perfectly natural-sounding native-like speech is not appropriate for use in CALL (Egan & La Rocca, 2000; Eskenazi, 2009), others argue that when TTS synthesis can outperform the more advanced learners it will be ready (Keller & Zellner-Keller, 2000); still others argue that when an expert speaker is not available, any spoken input no matter how poor the quality is acceptable (Delmonte, 2008). There is, however, little evidence to support either view as few evaluations have been conducted. In fact, only two evaluations of systems based on the current approach to TTS—namely concatenative synthesis—were found. The first of these studies (Kang et al., 2008) compared the comprehensibility of the speech generated by AT&T Natural Voices with that of natural speech by asking a group of Japanese learners of English to transcribe, translate, and rate the comprehensibility of a corpus of stimuli generated in both ways. It found little difference between the synthetic speech and the natural speech for word-length stimuli. The study, however, had a significant limitation; only one TTS system was evaluated. This is an important limitation because speech quality differs significantly across TTS systems and may even differ across different voices generated by the same system (Handley, 2006). Taking this into account, the second study, Handley (2009), evaluated a range of French

TTS systems. This study found that TTS systems which integrate nonuniform unit-selection synthesis (Henton, 2002), a specific form of concatenative synthesis, are ready for use in CALL applications which exploit the unique capacity of TTS synthesis to generate novel speech models on demand. The evaluators in this study were, however, teachers of French, not learners. If CALL applications integrating TTS synthesis are to move from prototypes to commercial or freely available applications (Holland & Fisher, 2008) and learners are to profit from the benefits that TTS synthesis can bring to CALL, further evaluations, in particular intervention studies with learners, need to be conducted.

Theory of Interpreting

MAGDALENA BARTŁOMIEJCZYK

Theory of interpreting is a dynamically developing field of study dealing with various aspects of oral and sign language translation in its several modes and a wide range of settings. The current output of publications (articles and books) in the field can be estimated at a few hundred a year. As opposed to the beginnings, when most studies were published in French or in English, today there is a much more heterogeneous scene, with a lot of recent studies being published exclusively in Japanese, Korean, or Chinese. Topics related to interpreting are popular choices for diploma, MA, and PhD theses. Interpreting research poses a number of challenges, many of which are unique to the field. The aim of this entry is to briefly present the major investigative approaches which have become established over time, giving some examples of prominent studies representing them.

Historical Perspective

Gile (1998), whose classification has gained a wide acceptance, enumerates four periods of research into interpreting. The first three of them are, in fact, limited to conference interpreting.

The “early writings period” covers literature from the 1950s and early 1960s. Its authors, such as Jean Herbert, Jean-François Rozan, and Gérard Ilg, mostly did not purport to write scientific texts, but rather to educate aspiring and beginning interpreters and maybe also inform the general public about the job of the conference interpreter and raise the consciousness of delegates making use of interpretation in meetings they attended. The handbook by Herbert (1956) may serve as a highly representative example. The very subtitle, *How to Become a Conference Interpreter*, expresses the purpose and spirit of the book. Statements were usually made on the basis of authors’ own experience as conference interpreters and/or interpreting teachers, but the methods and reasoning processes leading to these statements were not explained.

The “experimental period” (the 1960s and early 1970s) was characterized by much research done by psychologists and psycholinguists (e.g., David Gerver, Frieda Goldman-Eisler, Henri Barik), exploring aspects such as ear-voice span, pauses in delivery, the effect of noise on the interpreter’s performance. Practicing interpreters had a negative attitude to such studies, considering the experimental conditions too far from real interpreting experience.

The “practitioner’s period,” lasting from the late 1960s until early 1980s, saw the involvement of numerous interpreters and interpreting teachers into the discipline. Their studies were mostly not empirical, but speculative and theoretical, based on intuitions or on facts collected through nonsystematic observation. Prominent examples of works from this period include the publications of the Paris School, the most important representative of whom is Danica Seleskovitch. Her very influential book on conference interpreting (1978, first published 1968) discusses the controversial concepts making up her “*théorie du sens*,” such as deverbalization, a stage in the interpreting process between the reception of the source text and the production of the target text when absolutely no trace of the linguistic form of the source text is present in the interpreter’s mind. Another widely contested view

2 THEORY OF INTERPRETING

of this theory is that interpreting is language-independent, as both text comprehension and production happen spontaneously in any language of which the interpreter has the necessary command.

The “renewal period” started in the mid-1980s. Research is done mainly by practicing interpreters, who, in opposition to the previous period, are willing to incorporate findings and methods from other scientific disciplines (see the section on Interdisciplinarity below). The number of empirical studies is constantly rising. The scope of interest has widened considerably to include other modes and settings beside conference interpreting, such as court interpreting (e.g., Berk-Seligson, 1990), community interpreting (e.g., Wadensjö, 1998), medical interpreting (e.g., Angelelli, 2004b), and sign language interpreting (e.g., Metzger, 1999). One of the most popular theoretical concepts of this period is Gile’s (1995) effort models of consecutive and simultaneous interpreting, highlighting the problem of the interpreter’s limited processing capacity, which has to be strategically distributed among several concurring tasks (e.g., listening and analysis as well as note-taking during the first phase of consecutive interpreting).

Empirical Research

The process of introducing empirical methods into interpreting research was mostly initiated by scholars previously active in other disciplines, who brought with them their own methodological tools. Empirical research can be divided into two main types: experimental research and observational research.

The main advantage of experimental research is that it enables relatively high comparability of obtained data; for example, the same source text can be interpreted in the same booth by dozens of interpreters working under very similar conditions (although some factors, such as the participants’ motivation or present physical and mental condition, are beyond the experimenter’s control). The most important disadvantage of experimentation, however, lies in the fact that experiments take part in an artificial environment, which may lead to a situation that is not typical at all of the normal work environment. Consequently, it is important to stress the need to design experiments properly, that is, so as to make the materials and conditions as close to field reality as possible. It is unacceptable, for example, to use source texts of a type that is actually never interpreted. Many interpreters report that an unrealistic situation in an experiment makes for processes which depart considerably from those that occur during actual interpreting. Some practicing interpreters go so far as to reject all research based on experiments as devoid of ecological validity.

Another crucial problem of experimental research is the availability of participants. Professional interpreters rarely agree to take part in experiments, especially if they are offered no remuneration for the time and effort they would have to devote. As a result, numerous studies are based on data obtained from just a few participants, which makes any generalizations concerning the results difficult to justify. On the other hand, many experimenters base their studies on data provided by students of interpreting, who are much easier to recruit than professionals, especially for interpreter trainers. Such studies usually do not suffer from scarcity of participants, but the main doubt they raise is to what extent they actually reflect interpreting as performed on the market. It is not problematic as long as the researcher admits that the results obtained in such a study apply to interpreting trainees at a certain stage of interpreter education (corresponding to that of the participants); however, sometimes the results are presented as referring to professional interpreting as well. Bilinguals who are neither professional interpreters nor interpreter trainees are also sometimes asked to participate in experiments connected with interpreting. This makes sense in studies on modes of interpreting that are sometimes actually performed

by ad hoc interpreters (e.g., liaison interpreting by a bilingual child of immigrants in everyday situations, medical interpreting provided by a bilingual nurse for a foreign patient at hospital), but not in studies of conference interpreting. Bilinguals (e.g., advanced foreign language students) can certainly serve as a control group to compare some aspects of their cognitive processes and so forth with those of conference interpreters, but it is not acceptable to draw any conclusions concerning conference interpreting on the basis of interpretations provided by nonprofessionals.

Let us consider an early example of experimental research on interpreting. Gerver (1969) examined the effects of various presentation rates on the performance of interpreters. A native speaker recorded a French text (a fragment of a speech originally presented at a UNESCO conference on human rights) at a rate of approximately 120 words per minute. The tape was afterwards processed so that the speaking rate changed every 110 words. The successive fragments of the experimental source text had the speaking rates of 95, 112, 120, 142, and 164 words per minute. The speech was presented to 10 professional conference interpreters in a language laboratory. Half of them were asked to shadow it (i.e., repeat in French), and the other half to interpret it into English (their mother tongue). Both tracks of each recording were transcribed onto pen tracks obtained by means of an EEG pen recorder. This made it possible to measure speech time, pause time, and ear-voice span (e.g. the delay between a source text element and its counterpart). Ear-voice span was calculated for every fifth word. Additionally, the experimenter counted the number of correctly shadowed or interpreted words (literal translation was not necessary). The analysis showed marked differences between the performance of "shadowers" and interpreters. For example, the performance while shadowing deteriorated only at the highest speaking rate, whereas interpreting showed more omissions after each speaking rate change. Ear-voice span was longer for interpreting and it increased much more when the speaking rate rose than in the case of shadowing.

As regards the experimental design, the interpreting task must be evaluated as fairly realistic. The participants are conference interpreters. The source text is an authentic speech and it often happens that a speaker who delivers his or her speech quite slowly at the beginning speeds up as it progresses. Shadowing, however, is not an activity anyone is required to undertake for any practical reasons. Even as a pre-interpreting exercise it is highly controversial. Therefore it is not completely clear why it should be useful to compare it with simultaneous interpreting. As for analysis of the recorded material, counting correctly rendered words has since been replaced, in similar studies, with propositional accuracy score, a method considered to be better suited to analyze interpreting performance.

The main advantage of observational research is the authentic data it provides, whose representativeness for processes involved in interpreting cannot be challenged. Data from a number of case studies conducted in similar field conditions may lead to reliable generalizations. The main problem encountered by researchers engaging in observation, on the other hand, is access to authentic interpreting data. This is especially true of community interpreting, which often requires confidentiality. The interlocutors as well as the interpreter frequently object to recording and analysis of interpreted conversations. Therefore, observational studies of community interpreting are relatively rare, mostly conducted by experienced researchers, and typically published as a book (e.g., Wadensjö, 1998; Tryuk, 2004). As for conference interpreting, the number of source and target texts in the public domain, available for analysis, is constantly rising, as they are nowadays often broadcast on TV or placed on Web sites (e.g., debates of the European Parliament [EP] as well as their interpretations into official European Union languages can be found on the EP's Web sites). This makes observational studies feasible for students writing their BA or MA theses.

In their most typical manifestation, observational studies analyze recorded material (source texts and target texts) from an interpreted event. Pöchhacker's book (1994) can

serve as a good example of a comprehensive study based on a large corpus of observational data containing all source and target text for the English–German language pair from an international congress (over seven hours of original speeches and, correspondingly, of interpretations). The material enabled a detailed analysis of the interpreting situation (with features such as intertextuality and interaction between the speaker and the audience taken into consideration) as well as the interpretations (compared, whenever necessary, with the original speeches). The latter focused on two aspects: correctness and surface quality of the text (the profile of the text, speech length, speaking rate, pauses, instances of voiced hesitation, slips of the tongue, and self-corrections). The book shows the wide range of research directions and possibilities that a sufficiently large corpus of observational data can offer. However, many small-scale studies focusing on just one source text and its rendition (e.g., Pöchhacker, 1997, analyzing a nine-minute-long speech by President Clinton delivered in Berlin and its German interpretation) or a single interpreted event broadcast on TV (e.g., Kurz, 1993a, analyzing a US presidential debate) are valuable contributions too.

There are numerous studies employing questionnaires to investigate attitudes to different aspects of interpreting (especially quality), started by Bühler (1986), that must also be seen as examples of observational research (e.g., Kurz, 1993b). Angelelli (2004a) investigated whether interpreters' perception of their role depended on their social background and on the settings they worked in. She used comprehensive surveys (Interpreter's Interpersonal Role Inventory, IPRI, designed to measure interpreters' attitude toward their visibility in the interpreting process) on a large sample (293 participants) of conference, court, and medical interpreters from three countries. The book describes in detail the process of designing IPRI, from the search for similar instruments, through validation by discussing all the questions with 14 interpreters and pilot studies on 93 participants (trainee and professional interpreters), to the revision resulting in the final version with 13 background questions on social factors and 38 questions concerning visibility. The analysis of the responses to the questions and of additional, unsolicited comments revealed significant correlations between the interpreters' perceptions of their own visibility and factors such as their age, income, ethnicity, and the interpreting setting. Against the ingrained belief that an interpreter should act as a "ghost" (Kopczyński, 1994), the respondents working in all settings perceived themselves as having some visibility through their contribution to, among other factors, conversation management, cultural mediation, facilitating mutual respect and trust between the interacting parties. Medical interpreters claimed to have more visibility than court or conference interpreters.

Interdisciplinarity

A large portion, and probably even the majority, of interpreting research is closely linked, in one way or another, to other scientific disciplines, such as psychology, sociology, linguistics, or neurophysiology. Toury attributes this interdisciplinarity (or "multidisciplinarity," as some prefer to call it) primarily to the involvement of scholars whose original field of scientific interest was not translation studies, but who saw translation and interpreting as "new, intriguing areas of application for tools they already had at their disposal; areas which would be close enough to their 'mother' disciplines as well as sufficiently unexplored to warrant research with the help of these tools" (Toury, 1991, p. 45). Some of these scholars made a foray into interpreting research with one or two studies, and some have continued to regularly provide very valuable input over many years. A prominent example of the latter is Ingrid Kurz (formerly Pinter) from the University of Vienna, who started out in psychology, and was one of the first scholars to write a PhD on interpreting (in 1969).

Appreciating the crucial role other scientific disciplines play for translation studies, Malmkjær (2000) also notes some potential problems resulting from this phenomenon.

First of all, the level of knowledge may be insufficient, which applies equally to a translation scholar's knowledge of another discipline and to knowledge of translation studies acquired by a scholar from another discipline. Second, wholesale borrowing of a complete theory rather than just a research tool may lead to explaining translation in the service of the discipline from which the theory has been adapted rather than in the service of translation studies. Third, there is a danger that another discipline comes into the foreground to such an extent that translation is lost from sight. And, last but not least, the question of prestige can be considered, and a discipline providing insight for other disciplines will normally be seen as stronger than a discipline drawing from other disciplines. This section will discuss some examples of studies combining interpreting research with elements imported from other fields (for which Malmkjær's term "feeder disciplines" is used).

Psychology was the point of departure for the studies of conference interpreting in the "experimental period." This is not surprising, as most authors of these studies were trained psychologists. This wave of research is not without some serious shortcomings, but it launched empirical research into interpreting and probably represents the only period in its history when so many noninterpreters took an interest in interpreting. What attracted psychologists the most were the "mysterious" mental processes underlying listening and speaking at the same time in simultaneous interpreting. However, many of them failed to understand the strategic dimension of interpreting, for example the fact that an interpreter may choose to omit some portions of source text as redundant or having minor importance, or add something by way of explaining some culture-bound concepts.

Oléron and Nanpon's study (2002) was based on both observational and experimental data, although the second type was clearly given priority. The authors applied a quantitative analysis to their experimental material to determine, among other things, the delivery rate (number of words per minute) of speakers and interpreters. The most important part of their findings, however, concerns ear-voice span. Although the average ear-voice span lay somewhere between two and three seconds, it was discovered that its distribution was very asymmetrical, ranging from 0.5 to 11.1 seconds, and probably depended on many variables such as the speed of delivery or length and frequency of pauses in the original speech.

Valuable as this study is, due to the fact that it raised interest in interpreting as a research object and posed numerous important questions, it must be noted that it suffers from many methodological weaknesses, some of them typical of interpreting research done by noninterpreters. First of all, the number of participants was very small—only three professional interpreters. Second, the interpreting situation was unrealistic. In some parts of the experiments, the participants were requested to interpret strings of disconnected words and sentences, which never happens in practice. In the part in which they did interpret coherent texts, the texts were not of the type that would appear in conferences: fragments of Saint-Exupéry's book *The Little Prince* and the *UNESCO Courier*, chosen because they existed in a number of different language versions and thus enabled interpreting in several different language combinations.

Another popular feeder discipline for interpreting research is neurophysiology. For example, Fabbro, Gran, Basso, and Bava (1990) describe an experiment where simultaneous interpreting was studied by means of an experimental procedure known as verbal-manual interference paradigm. Fourteen advanced interpreting students with Italian as first language and English as second language were asked to interpret, while tapping a key connected to a counter, proverbs (which involves the meaning-based approach) and lists of words (which involves the form-based approach) in English and in Italian. The resulting interference did not show any pronounced difference between right and left hand, which suggests that simultaneous interpreting requires the involvement of both hemispheres. There was, however, a very considerable difference between interpreting with the meaning-based approach and with the form-based approach, the percentage of disruption for both hands

being much higher for the former condition. This suggests that meaning-based interpreting is a more demanding cognitive task.

The third crucial feeder discipline for interpreting studies is linguistics, or rather various branches of it. Cohesion studies, for example, have been of great interest to scholars engaged in research on interpreting. Shlesinger (1995) set out to validate empirically the hypothesis that a simultaneously interpreted text differs in the types and density of cohesive ties from the source text. In the experiment she conducted, 13 advanced interpreting students were asked to interpret from English into Hebrew an authentic impromptu speech in English. They did it twice in succession in a standard laboratory used for teaching simultaneous interpreting. The purpose of the second interpretation was to establish whether participants would make any nonrandom changes in the cohesive links due to the prior knowledge of the source text. Their interpretations were recorded and transcribed. The source text made extensive use of cohesion and contained cohesive links of four types: lexical cohesion, reference, substitution, and conjunction. The results of the experiment confirmed the initial hypothesis by revealing extensive shifts in each type of examined cohesive devices, particularly those which were seen as not indispensable to comprehend the informational content and those whose understanding required prior knowledge that the subjects did not have.

Another branch of linguistics particularly relevant for interpreting research is pragmatics. In Setton's highly technical book meant as "a bridge between interpretation studies and mainstream linguistics" (1999, p. xiv), Setton relied to a great extent on the findings of pragmatics, describing the effect of context rather than just source text on the target text. On the basis of a corpus of German-English and Chinese-English interpretations (obtained partly under real conference conditions and partly experimentally), he showed how the extralinguistic information available to the interpreters helped disambiguate and sometimes enrich the informational content present in the source message. World knowledge and situational knowledge both had a role to play in this aspect.

The 1990s and the 2000s saw the emergence of sociology and sociolinguistics as crucial feeder disciplines for interpreting research. Wadensjö (1998), for example, explored community interpreting as a special case of interaction, significantly different from conversations between two individuals. On the basis of observational data collected in authentic medical and legal settings involving interpreting between Swedish and Russian, she looked at interpreters as social actors and interpreting as "a matter of both linguistic and social competence" (1998, p. 14). She was among the first to challenge the prescribed nonparticipatory role of interpreters, which has since become the focus of a number of socially oriented studies dealing with the roles played by interpreters working in a wide range of settings such as police stations, courts, hospitals, and universities (e.g. Metzger, 1999; Roy, 2000; Angelelli, 2004a, 2004b).

Other fairly popular feeder disciplines include history (e.g., Bowen, Bowen, Kaufmann, & Kurz, 1995, discussing the role of interpreters in various historic events on the basis of information obtained from primary and secondary sources), and physiology (e.g., Klonowicz, 1994, investigating the management of energy resources in simultaneous interpreting by measuring blood pressure and heart rate of interpreters, as cardiovascular activity reflects effort and stress).

Conclusion

Interpreting research nowadays has many facets. It moves away from prescriptivism. It seeks to describe all interpreting modes and settings and all aspects of interpreting, including long-standing issues such as interpreter education or directionality (interpreting from

or into one's native language), as well as new topics such as performance of interpreters having no formal education in the profession. The proportion of empirical studies is on the rise, as is the interest in modes other than conference interpreting, the traditional domain of interpreting research. However, interpreting theory is divided, mainly into the psycholinguistic and sociolinguistic approaches, which look at different aspects of interpreting (information processing vs. interpersonal relations during interpreted interactions), and do not merge. Angelelli suggests the need for "an integrative theory of interpreting" that "will include and account for the discourse features of an interaction and the social context in which it is embedded, as well as the information processing aspect of the task" (2004a, p. 89).

Term Banks

HANNE ERDMAN THOMSEN

According to the international standard ISO 1087-2:2000, a term bank is a “data bank containing terminological data,” i.e., “data related to concepts or their designations.” It contains terminology relevant to one or more subject fields, and can thus be compared to a dictionary of (some) language for special purposes. Term banks are maintained in the context of an institutionalized organization such as a government agency or a department of a major company.

A term bank consists of one or more termbases or terminological databases. The format of a termbase will usually be an electronic database (or terminology management system—TMS) although during the early historical development of terminology work, term banks were in paper format (e.g., card indexes) and could be published as books.

The purpose of a termbase is usually to facilitate consistent and nonambiguous communication, including translation, within a specific subject field and/or for a specific purpose. Depending on the scope of a term bank, its termbases may treat a single field for a given company, or many specialized fields may be included to meet the needs of a broader audience.

Contents of Term Banks: Information Categories and Exchange Formats

The central information categories in a termbase or term bank are the term (or terms, in the case of synonyms) and the definition. To each of these, a number of related categories may be added, e.g., pronunciation, grammar, usage examples (term-related categories), or subject and semantically related concepts (concept-related categories). In a multilingual term bank, equivalent concepts in the languages treated are grouped together in one entry.

The international standard ISO 12620:2009 specifies criteria for creating a metadata registry designed to standardize data categories used in a wide range of language resources, including data categories for term banks and termbases. The online Data Category Registry, <http://www.isocat.org/>, includes several sets of data categories used in concept-oriented terminology databases. Designers of individual applications may collect their own subsets of this extensive inventory of items for use in their own work. ISO 30042:2008 describes formats for structuring and marking up data for exchange purposes.

Terminology Versus Lexicography

Term banks are compiled and organized according to the terminological or onomasiological working method, as opposed to dictionaries, which are compiled according to the lexicographic or semasiological method. The semasiological method is word-oriented, the point of departure is the expression, and the lexicographer finds and describes the various senses or meanings of each expression. The onomasiological approach, on the other hand, is concept-oriented. Here, the terminologist takes as point of departure the concepts that are relevant for a subject field and looks for the expressions that are used for designating each

2 TERM BANKS

Table 1 Lexicographic dictionary entry for *tape*

<i>tape</i>	
1.	A long narrow strip of magnetic material used for recording sound, pictures or information
2.	A cassette that contains tape in sense 1
3.	A long narrow strip of material with a sticky substance on one side. Synonym: adhesive tape; sticky tape
4.	A narrow strip of material that is used for tying things together or as a label
5.	A long narrow strip of material that is stretched across the place where a race will finish. Synonym: finishing tape
6.	A long narrow strip of material that has measurements marked on it and is used for measuring the length of something. Synonym: tape measure; measuring tape

of them, i.e., the designations. These different approaches result in two types of data collections, which differ with respect to the way entries are organized.

In a lexicographic dictionary the central organizational unit is the expression (headword or lemma), and each entry contains all possible senses associated with the headword as shown in Table 1, which quotes the entry for the word *tape* in a dictionary (the senses cited here are found in Hornby, 2005).

Table 2 Terminological entries containing the term *tape*

1	TERMS: tape SUBJECT: magnetic media DEFINITION: A long narrow strip of magnetic material used for recording sound, pictures or information
2	TERMS: tape SUBJECT: magnetic media DEFINITION: A cassette that contains a long narrow strip of magnetic material used for recording sound, pictures or information
3	TERMS: tape; adhesive tape; sticky tape SUBJECT: adhesives DEFINITION: A long narrow strip of material with a sticky substance on one side.
4	TERMS: tape SUBJECT: fasteners DEFINITION: A narrow strip of material that is used for tying things together or as a label.
5	TERMS: tape; finishing tape SUBJECT: racing DEFINITION: A long narrow strip of material that is stretched across the place where a race will finish.
6	TERMS: tape; tape measure; measuring tape SUBJECT: metrology DEFINITION: A long narrow strip of material that has measurements marked on it and is used for measuring the length of something.

In a term bank, the organizational unit is the concept—sense or *unit of knowledge* (ISO 1087–1:2000)—as shown in Table 2, which contains six entries corresponding to the senses in Table 1.

In the term bank, entry three above will be found when looking up any of the expressions *tape*, *adhesive tape*, or *sticky tape*. Note that a general dictionary would need to include all of the senses, whereas a term bank would include only the entries relevant for the subject fields covered in that collection; e.g., a term bank on textile manufacturing would contain only entry six.

Terminology Work

Systematic terminology work is described in the standard ISO 704:2009, originally based on work by Wüster (Wüster, 1931 and later), who showed how the analysis of relations between concepts provides a systematic overview of the terminology in a subject field.

The systematic method treats one well-defined subject at a time, for example, sound recording (*tape* 1) or tailoring (*tape* 2). Within a subject, a further systematic ordering is possible by showing the relations between the concepts in so-called concept systems such as the one shown in Figure 1, which was created using a TMS called i-Term.

Figure 2 shows how the introduction of characteristics for each concept makes it possible to identify relevant criteria of subdivision (white boxes) and get a better overview of the field.

An advantage of ordering concepts systematically is that it helps determine whether all relevant concepts have been included. Another advantage is that definition writing becomes much easier. The ideal definition in both lexicography and terminology is the intensional definition, which cites the superordinate concept and the delimiting characteristics. Without a concept system, it is often difficult to identify the immediately superordinate concept, as can be seen if one tries to construct a concept system from dictionary entries.

Monolingual and Multilingual Term Banks and Termbases

Term banks, like dictionaries, may be mono- or multilingual. In the case of a multilingual term bank, concepts may be conceived as either language-independent or language-dependent. In the language-independent view, each entry in the collection contains one concept, which may be described by (identical) definitions in each of the languages covered. In the language-dependent view, however, each entry contains one concept per language,

Figure 1 Concept system showing types of measuring tape

Figure 2 Concept system with characteristics

and if the concepts are not fully equivalent, notes that explain these differences may be added.

Usually the language-independent view can be advocated within technical fields, as these are developed in international contexts. An example could be *tape* in the field of sound recording. But in term banks covering fields such as educational systems, the language-dependent view can account for the differences and for incomplete equivalence between concepts in two languages. In fact, *culture-dependent view* would be a more correct term: The education systems in Canada and Switzerland differ, though one of their languages is the same (French).

National or Supranational Term Banks Versus Organization-Specific Ones

The most prototypical and classical organization to maintain a termbase is a translation provider, either a translation company, an individual translator, or the translation unit within a larger company or organization. In these cases termbases are used to ensure consistency, e.g., within one (large) translation task, especially if more than one translator is involved, across product releases or several versions of the same document, and in the case of translation companies, a termbase may be used to keep track of customer preferences regarding the choice between synonyms.

Termbases are maintained by both public and private organizations. Typically, in countries with more than one official language, such as Canada or Switzerland, termbases or even term banks are maintained by government agencies responsible for language and translation, and likewise in international organizations such as the European Union or United Nations. Some of these term banks are publically accessible, e.g., IATE and Termium (see the list of online resources). Some national term banks may focus on the (single) national language while still including translations for selected areas into some languages, either minority languages (e.g., Sami in Sweden) or some of the internationally dominant or important languages (e.g., English, French, Chinese).

Private companies may primarily need term banks to ensure consistency in product development, marketing, and localization of products. Hence, large information technology

companies such as IBM, Nokia, and SAP maintain term banks and processes for terminology management. Term banks may also be used to minimize misunderstandings due to ambiguity within the company itself, and in large, international companies, multilingual term banks can be crucial for ensuring unambiguous communication across languages and cultures. There are even examples of mergers between (monolingual) companies with term banks, where the contents of the two term banks showed clear differences in the understanding of some terms—differences that could have led to misunderstandings and hostility if they had not been handled.

Terminology Management Systems (TMS)

Some term banks are maintained in simple documents or spreadsheets, but a proper database is much more efficient. There exist off-the-shelf TMSs, both free and commercial, and some larger companies and organizations develop their own systems.

A TMS may be integrated with a translation memory system (TM) but not all systems are. In cases where the TMS integrated with the preferred TM system does not meet the demands set up for terminology work in the organization, it is possible to use one TMS for terminology work and export data to the TM-integrated one.

In order to allow for this, it is necessary to ensure that the information categories (or data categories) in the two TMSs are the same and that a proper exchange format is described.

Current Research

Current research within applied terminology focuses on the development of automatic methods for terminology work, such as term extraction and extraction of semantic relations between concepts. Theoretical research issues in terminology include relation types, similarities between relations and characteristics, and the relationship between concept systems and various other types of ontologies.

Terminology and Data Encoding

MARIE-CLAUDE L'HOMME

Terminology is “the study and field of activity concerned with the collection, description, processing and presentation of terms” (Sager, 1990, p. 2). A term can be defined as a lexical unit that conveys a specialized meaning (a meaning that is related to a field of knowledge, such as accounting, biology, computer science, history, or physics). Terminology shares many characteristics with lexicography, but has developed over the years as a separate field of activity and produces its own descriptions. Terminological descriptions can appear in specialized dictionaries (in printed or electronic form), large term banks, or in-house terminological databases.

Computer applications are used at nearly all stages of terminology work (term identification in running text, collection of information about these terms, encoding of data; L'Homme, 2010). This entry will focus on some of the technologies that are available today for the last stage, that is, encoding terminological data. However, before doing so, a brief historical account will be presented and a few basic principles on which the encoding of terminological data relies will be described.

A Brief Historical Account

Storage of terminological data in electronic form started as early as the 1960s, long before general language dictionaries were computerized. Terminological databases were set up by various private and public organizations (see Rondeau, 1984) and have been used to store, manage, and retrieve terminological data ever since. Although their design has changed drastically, some of these early databases are still updated today and can be accessed on the Web (e.g., IATE, <http://iate.europa.eu>; *Grand dictionnaire terminologique*, www.granddictionnaire.com; Termium Plus®, <http://www.termiumplus.gc.ca/site/termium.php?lang=eng&cont=001>). From the very beginning, databases have been considered as the proper medium for storing terminological data, and much effort was devoted to devising efficient methods to organize this data, whereas computerized general language dictionaries often consisted of an electronic copy of printed material.

Over the years, terminological repositories have gone through a number of important technological changes. The first ones to be launched were managed by large organizations and were first stored on servers only accessible via a modem connection. During the 1980s, some were distributed on CD-ROMs that needed to be updated. Data structures commonly used were classic databases or indexed text. Nowadays, terminological data are placed in more flexible environments, such as relational databases or structured document formats using markup languages (e.g., XML, eXtended Markup Language), and can be developed by any user interested in storing this kind of data. In addition, terminological data can be stored on electronic media for different purposes: disseminating information about specialized terms in the Internet, storage of terminological data for in-house use, or automatic retrieval of terminological equivalents in machine or computer-assisted translation.

Terminological Data: Basic Principles

Although the technology available for encoding terminological data has evolved over the years as pointed out in the previous section, the organization of terminological data per se (type of information encoded, number of fields used to encode this data, etc.) has remained basically the same; at least when compared to that of lexicographical data.

Terminology makes a clear distinction between the *concept* and the *denomination* used to refer to this concept. The concept is the content of the linguistic sign and its delimitation is based on its position in the knowledge structure of a specific subject field (often this position is defined by the experts in the said field). The denomination refers to the linguistic form and to the formal facet of the linguistic sign. The combination of a concept and a denomination corresponds to a *term*.

In a terminological repository, one entry describes a specific concept and all the denominations used to designate this concept—defined as true synonyms—are listed in the same entry (e.g., *email*, *e-mail*, *electronic message* will appear in an entry devoted to the concept “e-mail”). Most terminological databases are bilingual or multilingual; hence, the listing of all denominations applies to all languages considered (e.g., EN: *email*, *e-mail*, *electronic message*, *electronic mail*; FR: *courriel*, *courriel électronique*, *mél*, *mail*, *email*; ES: *correo electrónico*, *mensaje electrónico*). If the same linguistic form refers to two separate concepts, it appears in different entries. For example, *valency* refers to different concepts in the fields of linguistics and chemistry and will thus appear in two different entries.

The data categories found in entries are quite similar in most terminological repositories (Sager, 1990; Cabré, 1999; Pavel & Nolet, 2001). As can be seen in Figure 1, they consist of: a subject field label, a language identifier, a headword (generally the preferred term), other linguistic forms used to refer to the concept (synonyms, abbreviations, and deprecated terms—i.e., those not recommended for use), grammatical information, usage labels, a definition, contexts (textual extracts in which a term is used); observations (an optional data category designed to supply additional information on the concept or one of the terms listed in the entry), and references.

In addition to the standard data categories listed in the previous paragraph, some terminological descriptions have started to supply other kinds of information. Below are a few examples of the kinds of recent additions to terminological repositories:

- Illustrations: Terminological entries can contain pictures or a graphical reproduction of the concept being described.
- Related terms: Terminological entries can highlight specific relationships between the term considered in the entry and other closely related terms in the same subject field. For example, in an entry describing the term *mouse*, the following links can be provided:

Subject field: telecommunications	
English	Français
email, n.	courrier électronique, n. m.
Var. e-mail	Syn. courriel
	Not recommended: email, mail
Definition: A digital message sent by a user of a computer network to another user by means of electronic transmission of data.	
Context: Tons of emails are sent each day and they become a very common target for spammers (THSM209).	

Figure 1 A term record

- *peripheral device*: a generic term (a hyperonym);
- *optical mouse*, *mechanical mouse*, *cordless mouse*: specific terms (hyponyms);
- *button*, *scroll wheel*: parts of the *mouse* (meronyms); and
- *cursor*, *pointer*: the objects on which the mouse acts (arguments).
- Collocations or typical phrases: Some entries contain an additional data category for combinations in which terms typically appear. For example, in an entry describing the term *email*, the following verbal collocations can be listed: *write an email*, *send an email*, *delete an email*, *forward an email*. Similarly, in the term record for *mouse*, the following collocations can appear: *move a mouse*, *click on something with a mouse*.

Encoding Terminological Data in Electronic Form

The remaining sections present the most common technologies used for storing and organizing the terminological data described in the previous section.

Flat and Relational Databases

Since many terminological descriptions focus on standard data categories, the first and still most commonly used electronic repository for encoding terminological data is the database. In a database, the information is structured in accordance with the following principles (see Figure 2):

- The data is structured in a systematic way for all concepts described; in other words, the data structure remains the same for all the concepts described throughout the database.
- The sum of information related to a concept is described in a record.
- Each piece of information is placed in a separate cell called a *field*.

In a database, since the data are structured in separate fields, each piece of information can be manipulated separately for specific purposes: data extraction, searches, sorting according to different criteria, and so forth. This is a clear advantage over printed media in which data can only be accessed through one (or sometimes two) data categories.

Nowadays, databases are relational, and this allows developers to place the information linked to a specific concept in separate data structures to overcome problems related to the overload of information in the same record. For example, the information on the terms *email* and *mouse* could be dispatched in three separate data structures: The first one would contain linguistic information, the second one contexts, and the third one collocations (see Figure 3). A formal mechanism—namely a *relation*—will ensure that the information relevant to a specific term or concept can be found in the different structures. In Figure 3, the relation is made possible since the fields “English entry” that appear in the three data structures contain identical character strings.

Subject field	English entry	English variant	English definition	English context	French entry	French synonym	French not recommended
Telecommunications	email	e-mail	A digital message ...	Tons of emails ...	courrier électronique	courriel	email, mail
Computing	mouse		A peripheral device ...	The movement of the mouse ...	souris	souris informatique	

Figure 2 A data structure in a terminological database

4 TERMINOLOGY AND DATA ENCODING

Data structure 1: Terms and linguistic information

English entry	Grammatical information	English variant
email	n.	e-mail
mouse	n.	

Data structure 2: Terms and contexts

English entry	Context	Reference
email	Tons of emails are sent each day and they become a very common target for spammers.	THSM209
email	You can send this email safely to some friends.	GMLD222
email	Do not respond to all emails you receive, especially those sent by someone you do not know.	DNBL008
mouse	The movement of the mouse over the surface is mirrored by a pointer on the monitor.	DEVICE02
mouse	Common input devices are the mouse and the keyboard.	DNGJFI29
mouse	Once you have installed your wireless mouse, you can start moving the pictures on the screen.	FJDSLI98

Data structure 3: Terms and collocates

English entry	Collocation	Collocate
email	send an ...	send
email	write an ...	write
email	forward an ...	forward
email	delete an ...	delete
mouse	move a ...	move
mouse	click on something with a ...	Click

Figure 3 Different data structures in a relational database

Relational databases are now commonly used to organize terminological data related to different languages. They become very convenient if several languages are taken into account: The data specific to each different language can be clearly separated from the data which are linked to the concept and assumed to be language-independent (see Figure 4).

Structured Document Formats

Increasingly, terminological data can be organized in structured documents and organized using *markup languages*, such as XML. In structured documents, data are structured by means of tags; these are placed within the text. The data structure is superimposed on the data, which no longer need to be placed in a separate environment as is the case in databases. Figure 5 shows how simple terminological data can be organized using XML tags.

One advantage structured documents have over standard databases is the fact that tags can be represented in a hierarchy, allowing data to be structured at different levels. This functionality can be used for different purposes: Figure 6 illustrates a case where the definition is further structured in order to signal related terms.

Structure 1: Concept

Concept	Subject field	Definition
email	Telecommunications	A digital message sent by a user of a computer network to another user by means of electronic transmission of data.

Structure 2: English terms

Concept	English entry	Grammatical information	Usage note
email	email	n.	Preferred term
email	e-mail	n.	Variant

Structure 3: French terms

Concept	French entry	Grammatical information	Usage note
email	courrier électronique	n. m.	Preferred term
email	courriel	n. m.	Synonym
email	email	n. m.	Not recommended
email	mail	n. m.	Not recommended

Structure 4: Spanish terms

Concept	Spanish entry	Grammatical information	Usage note
email	correo electrónico	n. m.	Preferred term
email	mensaje electrónico	n. m.	Synonym

 - ⇒ Mouse (“used to move and point on objects in the graphical interface”)
 - Optical mouse
 - Mechanical mouse
 - Etc.

Figure 7 Classes in a hierarchy

Repositories for Knowledge: Ontologies

In specific projects, terminological data can be stored in *ontologies* (Gómez-Pérez, Fernández-López, & Corcho, 2004). (The expression *terminological knowledge base* is sometimes preferred in terminology circles; Meyer, Eck, & Skuce, 1997.) Ontologies are sophisticated environments in which pieces of knowledge (which can be viewed as concepts as terminology defines them) are represented in such a way that the relationships between them are formally linked and interpreted. Once knowledge related to a specific domain is properly represented in this kind of environment, automatic reasoning can be applied to specific aspects of this knowledge. Ontologies can be very complex, and only a few basic principles on which they rely will be mentioned here.

An ontology represents concepts, their relationships and their properties. Concepts are organized hierarchically in the form of classes (see Figure 7) and can be linked to a number of instances (i.e., individual realizations of concepts). Each class is assigned a number of properties that should apply to all members of this class. The properties assigned to the mother classes are said to be *inherited* by daughter classes. Of course, even in restricted fields of knowledge, concepts can seldom be organized in a simple hierarchy, and ontologies are equipped with devices allowing sets of restrictions to be specified.

Concluding Remarks

This entry has described the basic principles according to which terminological data are represented, and has given a quick overview of the different technologies that can be used for that purpose. Once stored in any of the formal environments described above, terminological data can lend themselves to all sorts of exploitations: retrieval of specific sets of data for presentation in a printed dictionary, extraction of equivalents for machine or computer-assisted translation, automatic reasoning on knowledge in a domain, and so forth.

Theses and Dissertations in English for Specific Purposes

BRIAN PALTRIDGE

There are a number of discussions in the literature of the issues that second language students face when writing a thesis or dissertation in English. One key issue that arises in this literature is the difficulty that many students face in meeting the demands of the kind of writing required of them at this particular level of study. It is not always clear to them whose responsibility it is that their piece of writing meets the requirements of their level or area of study. This is made more difficult for students who do not have an English-speaking background by their lack of familiarity with the conventions and expectations of thesis and dissertation writing in English. As Dong (1997, p. 10) notes, writing a thesis or dissertation

involves learning a new set of academic rules and learning how to play by these rules. Often these rules change from discipline to discipline, and the audience and the purpose of writing vary according to each writing context. For non-native students, the mismatch of writing difficulties and expectations operating in their home countries compound their writing difficulties.

As Johns and Swales (2002) have pointed out, even the basic outline of a thesis or dissertation is a complex issue that needs to be negotiated among supervisors and students, and subfield, methodology, and choice of theory are often strong determining factors in terms of what the thesis or dissertation might look like. It is not the case that there is simply one way to write a thesis or dissertation that is acceptable in every area of study. Notwithstanding, there are certain conventions that theses and dissertations are expected to follow. These are, however, often not clearly stated and may be quite different from the conventions and expectations governing how this kind of text might be written in the student's first language and culture.

Furthermore, some students from a non-English-speaking background may bring with them different expectations and perceptions of the supervision process based on the academic conventions and cultures of their country of origin, such as who is responsible for choosing the research topic, who is responsible for the final content of the dissertation, and who is responsible for the quality of the writing of the final product (see Paltridge & Starfield, 2007, for further discussion of these issues). It is important, however, not to take a stereotyped view of how a student from one language and culture will necessarily write in another. One of the key findings of research in this area is that all students are individuals with their own preferences and ways of writing, which may or may not be influenced by their first language and culture.

There are many factors that influence the decisions a student makes while writing a thesis or dissertation in English. These include the orientation of the project they are describing, the student's perceptions of the audience of their text, the discipline in which the student is writing, and the values and expectations of the academic community at which the text is aimed. Paltridge (2006) provides an analysis of the context of thesis and

dissertation writing, discussing the range of factors that impact on how the text is written, how it is read, and, importantly, how it is assessed. These factors include the social and cultural context in which the thesis or dissertation is being written (along with factors such as the setting, focus, and perspective of the text); the purpose and intended audience for the text; the relationship between writers and readers of the text; expectations, conventions, and requirements for the text; the background knowledge, values, and understandings it is assumed the writer shares with their readers; and the relationship the student's text has with other texts. Each of these is important as they all, in their way, have an impact on what the student writes, and the way they need to write it.

The issue of disciplinary discourses has been taken up by researchers such as Hyland (2004) who discusses the relationship between the cultures of academic communities and their discursive practices. Through close textual analyses, he provides insights into the social practices and institutional ideologies of different academic communities and what this means for writing texts such as theses and dissertations. Writers such as Prior (1998) have carried out ethnographic examinations of contextual issues in thesis and dissertation writing. As Prior's work reveals, disciplinary enculturation is very much a case of ongoing negotiation between students and their professors, mentors, and peers, rather than just a case of learning the language and culture of the academy.

Dudley-Evans (1999), Thompson (1999), and Dong (1998) describe a number of types of thesis and dissertation that occur in different academic disciplines. Dudley-Evans terms the typical "IMRAD" (introduction–methods–results–discussion) type of dissertation a "traditional" dissertation. Thompson further refines this category, dividing traditional dissertations into those that have "simple" and those that have "complex" patterns of organization. A further kind of dissertation is the "topic-based" dissertation. The "topic-based" dissertation typically commences with an introductory chapter, which is then followed by a series of chapters that have titles based on subtopics of the topic under investigation. The dissertation then ends with a conclusion chapter. Dong (1998) describes doctoral dissertations that are based on a compilation of publishable research articles, which are quite different from other sorts of doctoral dissertations. The research article chapters are more concise than typical dissertation chapters with less of the "display of knowledge" that is often found in a doctoral dissertation. In terms of audience, they are written more as "experts writing for experts," than novices "writing for admission to the academy." In this sense, they contrast with the "traditional" type of dissertations described by Dudley-Evans and Thompson.

Paltridge (2002) extends the work on thesis and dissertation types in a project which explored the extent to which published advice on the organization and structure of theses and dissertations concurs with what happens in actual practice. The study examined guides and handbooks which focus on thesis and dissertation writing and postgraduate research. Only a few of the books examined devoted a substantial amount of space to this topic. A wider range of dissertation types was found than the guides and handbooks would suggest occurs. None of the books that were examined contained all of the dissertation types described by Dudley-Evans, Thompson, and Dong even though all of these types were found in the data set that he examined.

Other discourse-related research into thesis and dissertation writing has investigated the introduction to theses and dissertations, the literature review, dissertation acknowledgments, discussion sections, and conclusion chapters. Researchers have also examined metadiscourse, authorial identity, textual borrowing, qualitative dissertation writing, voice, identity, argument, audience, and rhetorical awareness in second language thesis and dissertation writing.

Important books which describe the experiences of second language thesis and dissertation writers include Casanave's (2002) *Writing Games* and Casanave and Li's (2008) *Learning*

the Literacy Practices of Graduate School. In her opening chapter to this latter volume, Casanave points out that, for second language doctoral students, it is not just a matter of becoming proficient in English; it is a matter of learning how to participate, fully, in an academic community of practice and learning what all of this entails. Other authors in Casanave and Li's volume discuss identity construction in the new and different community of practice, learning from mentors, working with supervisors, writing qualitative research, and "how to survive" graduate school. As Tardy (2009) points out, most students have not been through this experience before and need to learn the conventions, expectations, and procedures of the task they are engaged in, at the same time as they are carrying it out.

A number of authors have also discussed the teaching of thesis and dissertation writing (see e.g., Paltridge, 2003; Starfield, 2010). Swales and Feak's (2004) *Academic Writing for Graduate Students* and their (2000) *English in Today's Research World*, as well as their expansions of this book (Feak & Swales, 2009; Swales & Feak, 2009) are especially important texts. Although not written as research monographs, these books are strongly influenced by research into the thesis and dissertation genre. *English in Today's Research World* pays particular attention to genre networks, that is, the sets of genres that postgraduate students need to be able to produce, and participate in, in the course of their study and beyond. It also provides detailed advice on particular parts of theses and dissertations such as the literature review, dissertation abstracts, and acknowledgments.

There are a number of directions which future research on this topic might explore. The area of research known as "contrastive rhetoric," or more recently "intercultural rhetoric," compares genres in different languages and cultures. Many studies in this area have focused on academic writing in general, although many fewer have compared thesis and dissertation writing across cultures.

A further useful development in dissertation-writing research, which could be further expanded to thesis and dissertation writing, is Swales's (1998) notion of *textographies*. A textography is an approach to the analysis of written texts which combines elements of text analysis with ethnographic techniques in order to examine what texts are like, and why. That is, it aims to get an inside view of the worlds in which the texts are written, what guides the writing, and the values that underlie the texts that have been written. This approach provides both a situated and contextualized account of academic writing that would be useful to future dissertation writers (see Paltridge, 2008, and Paltridge, Starfield, Ravelli, Nicholson, & Tuckwell, in press, for further discussion of this).

The use of literacy autobiographies (Starfield, 2010), and literacy portraits (Casanave, 2002), is a further research direction that is being taken up in thesis- and dissertation-writing research. These kinds of accounts are able to provide important insights into second language dissertation writers' worlds in that they "allow us to recontextualise discourses that position international students and others from non-English speaking backgrounds as different, or lacking and come to understand them as having achieved and succeeding in meeting great challenges" (Starfield, 2010, p. 138). In a study that describes a dissertation-writing class which had a mix of native- and non-native-speaker students, one native-speaker student said:

Sometimes the non-native speakers were much more advanced than I was. They came much better prepared and were much more on track than I was. I have a lot of respect for their ability. I don't understand what the difference is. We all knew nothing when we came in. It's not English that is the problem. Maybe they had grammatical mistakes, but I had them as well. It's more about how you can sort, analyze, and approach the whole thing, not just whether you can write grammatically correct sentences. (Paltridge, 2003, p. 89)

It is important to remember, then, that in dissertation-writing research it's "not all about language" and that second language students are no less capable than native-speaker students of being successful dissertation writers (and doctoral researchers) in English-language academic settings.

Thibault, Paul

KAY L. O'HALLORAN

Paul J. Thibault (b. 1953) has a distinguished research background in general and applied linguistics in areas relating to the sociocultural and biological-physical dimensions of human meaning-making activity, which he has developed into a transdisciplinary field of knowledge involving social semiotics, cognitive science, psychology, biology, and complex dynamical systems theory.

Thibault was awarded the degree of BA honors (Class 1) in English language and linguistics at the University of Newcastle in New South Wales, Australia, and the degree of PhD at the University of Sydney, Australia, in December 1985. His PhD thesis was supervised by M. A. K. Halliday in the Department of Linguistics. Following this, he held posts at the University of Bologna, Italy (1985 and 1990–2), University of Sydney, Australia (1986–9) and University of Verona, Italy (1987–9) before being appointed Associate Professor in English Language and Linguistics at the University of Padua, Italy, in 1992.

In these early stages of his academic career, Thibault developed a “praxis-based” approach to social semiotics for exploring the relations between social processes, textual products, and signs in *Social Semiotics as Praxis* (Thibault, 1991). Thibault also explored general philosophical questions in relation to language and communication, including an in-depth re-examination of Ferdinand de Saussure’s social-semiological metatheory in relation to modern linguistic and social theory in *Re-reading Saussure. The Dynamics of Signs in Social Life* (1997).

Thibault remained in Italy until 2004, as associate professor in English language and linguistics at the University of Venice, Italy (1995–2004) and visiting associate professor of English language and linguistics in the Faculty of Education Sciences, University of Bologna (1998–2001). In November 2002, he won a national competition in Italy for the position of full professor (although this post was not taken up). From January to December 2002, he was visiting professor in the Department of English, Lingnan University in Hong Kong. In September 2004, Thibault was appointed as tenured professor of Linguistics and Media Communication at Agder University College, Kristiansand, Norway. In addition, he was visiting professor in the Faculty of Education at the University of Hong Kong (2009–11) and honorary professor in the School of Foreign Languages and Literatures at Beijing Normal University (from 2006).

During this time, Thibault explored the role of the body–brain complex in social meaning-making practices in *Brain, Mind, and the Signifying Body* (2004a) with the aim of developing an “ecosocial semiotics” which, following Jay Lemke, was capable of reconnecting body–brain processes and interactions to the social and cultural practices which directly act upon and affect human bodies. Thibault saw that many of the fundamental questions concerning ecosocial semiotic theory could only be addressed through an engagement with foundational concepts and questions of both the social and the life sciences, which had been given new direction and impetus by the development of complex adaptive dynamic open systems theory. The key features of this new perspective were the inclusion of time, irreversibility, the embedding of systems in higher-scalar environments, and individuation. Thibault (2004a) theorized the inseparability of the semiotic-discursive and physical-material cross-couplings and dynamics and the materiality of the body as playing a central role in social meaning-making activity.

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1212

Thibault describes how the linkages of semiotic integration of meanings across different space and time scales relate to the structure of agency and consciousness in *Agency and Consciousness in Discourse* (2004b) by connecting his theory of ecosocial semiotic systems to consciousness as a complex adaptive system which operates on many different levels of brain–body–world relations. In the process of developing his new theory of agency and consciousness and their formation across different scalar levels of semiotic and material organization, Thibault reviews and evaluates the contributions of linguists, psychologists, biologists, semioticians, and sociologists such as Basil Bernstein, Mikhail Bakhtin, J. J. Gibson, Michael Halliday, Walter Kauffman, Lakoff and Johnson, Jay Lemke, Jean Piaget, Stanley Salthe, Colwyn Trevarthen, and V. N. Vygotsky.

In these two major works, Thibault (2004a, 2004b) transcends text- and discourse-based theories which locate the architecture of language and its functionality in abstract verbal-textual patterns to “linguaging behavior” which is related to human mental and somatic capacities. Thibault views languaging as a culturally shaped extension of our neurobiological capacities, rather than a tool that is instantiated from an abstract system of options. Moreover, languaging behavior is seen to be embedded in action and perception, rather than existing as reified text-internal verbal patterns (Thibault, 2011).

With Anthony Baldry (University of Messina, Italy), Thibault has codeveloped since 1997 the online multimodal concordancing and authoring system MCA (MCA.unipv.it), as part of a major Italian national research project CITATAL and LINGUATEL, researching on corpus linguistics, text analysis, translation, multimodality, and language learning. Baldry and Thibault’s (2006) *Multimodal Transcription and Text Analysis* explores multimodal theory, transcription, and analysis across print and digital media from a social semiotic perspective, advancing Thibault’s conception of scalar hierarchies in multimodal meaning-making practices, and has become a standard text for those engaged in multimodal studies.

In addition, Thibault has written numerous journal articles and book chapters including research on child language development, narrative discourse and its grounding in prior nonverbal perceptual and semiotic modalities, embodied interaction and face-to-face communication as action systems in both human and nonhuman cases and, more recently, investigations on narrativity, self, and hypertext and transformational and transcendental aspects of grammar in relation to our experience of the world.

Thibault’s research trajectory and associated works illustrate the breadth, depth, originality, and richness of his contributions to applied linguistics.

Thinking for Speaking in Second Language Acquisition

TERESA CADIerno

Introduction

The “thinking for speaking” (TFS) hypothesis is concerned with the possible effects of language on the kind of thinking that occurs online in the process of using language. This hypothesis constitutes a modified version of the linguistic relativity hypothesis which relates language to a particular worldview. The TFS hypothesis was proposed by Slobin (1996) on the basis of research conducted on first language (L1) acquisition, but in the past few years the implications of the hypothesis for adult second language (L2) acquisition have started to be investigated in systematic ways.

Thinking for Speaking and Linguistic Relativity

The linguistic relativity hypothesis, that is, the possibility that language can influence thought, has constituted an important part of Western intellectual discussions over the centuries. The hypothesis is, however, best associated with the work of Whorf (1956), who claimed that as language affects the way we think, speakers of different languages must arrive at somewhat different views of the world.

Recently, Slobin has proposed a more cautious and dynamic version of the linguistic relativity hypothesis—the TFS hypothesis—where he replaces the abstract entities “thought” and “language” with the names of the activities “thinking” and “speaking” in order to draw attention to the mental processes that take place when speakers formulate utterances. In other words, rather than focusing on the potential influence of language on speakers’ general thought, that is, on speakers’ patterns of attending to, categorizing, and remembering objects and events, the TFS hypothesis is concerned with the mental processes that occur during the act of interpreting and verbalizing experience.

Specifically, Slobin’s TFS hypothesis focuses on the effects that the obligatory grammatical categories of a language may have in directing their speakers’ attention—while speaking—to the dimensions of experience that they encode. Crosslinguistic research has shown that languages present striking variations in this respect. For example, when speaking about past events, speakers of Turkish are obliged to choose between two past tense inflections, one for witnessed events and another one for unwitnessed events (Slobin, 1996). Great variation has also been documented in how languages express spatial relationships. For example, whereas in English placing an apple in a bowl or placing a video cassette in its case are described by their native speakers (NSs) as putting one object *in* another, in Korean both events are described with different verbs, as this language makes an obligatory distinction between a loose-fitting type of relation (an apple in a bowl) and a tight-fitting one (a video cassette in its case) (Bowerman, 1996).

What the above examples show is that at the moment of linguistic encoding, one must fit one’s thoughts into the available lexicogrammatical forms of the particular language that one is speaking. According to the TFS hypothesis, the language that we speak directs

us to attend—while speaking—to the dimensions of experience that are coded in its grammatical categories (e.g., whether an event has been witnessed or not by the speaker, or whether the objects we are describing are in a tight or loose type of relation), and over time, this repeated attention leads to specific rhetorical styles.

Thinking for Speaking in L1 Acquisition

Empirical support for Slobin's TFS hypothesis has mostly come from crosslinguistic research examining how NSs of different languages—both children and adults—talk about the conceptual domain of motion (e.g., Berman & Slobin, 1994; Slobin, 1996, 2004). This research has been inspired by Talmy's (e.g., 2000) typological work, which has identified two main types of languages according to how the semantic components of a motion event (such as path and manner) are lexicalized, that is, expressed in surface linguistic forms.

Satellite-framed languages (S-languages) such as the Germanic and Slavic languages tend to encode path (i.e., the direction of motion) in satellites such as verb particles (e.g., *down*, *out*, and *up*), and motion and manner (i.e., the way in which the motion is performed) in the main verb. In contrast, verb-framed languages (V-languages) such as Romance and Semitic languages tend to express motion and path in the main verb (e.g., *subir* 'go up', *bajar* 'go down'), and manner of motion in a separate constituent such as an adverbial or gerund.

- (1) The bottle floated out of the cave.
- (2) La botella salió de la cueva flotando.
'The bottle went out of the cave floating.'

Example (1) illustrates how English, an S-language, expresses manner of motion in the verb *float*, whereas path is coded in the verb particle *out*. Example (2), on the other hand, shows how Spanish, a V-language, codes path of motion in the verb *salió*, whereas manner of motion is expressed in the gerund *flotando*.

Crucially, previous studies have shown that NSs of typologically different languages (S- vs. V-framed languages) tend to focus on different aspects of motion events in narrative discourse (see Slobin, 2004, for an overview). For example, speakers of S-languages tend to encode more detail explicitly about the movement along paths, leaving the settings to be inferred, whereas speakers of V-languages tend to encode more detail explicitly about the scene setting, leaving the trajectories to be inferred. Examples in (3) and (4) illustrate these tendencies in English and Spanish:

- (3) The deer threw him off over a cliff into the water.
- (4) Lo tiró. Por suerte, abajo, estaba el río. El niño cayó en el agua. (Slobin, 1996, p. 204)
'(The deer) threw him. Luckily, below, was the river. The boy fell into the water.'

In (3), the detailed trajectories described allow the listener to infer that there is a cliff above the water, whereas in (4), the static description *below, was the river* allows the listener to infer that the trajectory went from some elevated place down to the water. These tendencies can be attributed to the grammatical resources that are available for the expression of motion in the two types of languages, as English, but not Spanish, allows for compact expressions such as (3) where complex trajectories are described by way of accumulating several path satellites within a single clause.

Important differences have also been found with respect to the expression of manner of motion. The lexicons of S-languages contain a wider variety of manner of motion verbs

(e.g., *dash*, *swoop*, *scramble*), and the speakers of these languages tend to provide more frequent and varied manner information than speakers of V-languages do when describing motion events. Speakers of S-languages thus seem to pay more online attention to this aspect of experience while talking about motion than speakers of V-languages do.

In addition to the differences just mentioned, research examining the simultaneous use of speech and gestures (e.g., Kita, 2009) has revealed crosslinguistic differences in the gestures employed by NSs of typologically different languages. For example, Turkish speakers express path and manner in separate clauses and perform separate path and manner gestures, whereas English speakers express path and manner in one clause and may conflate them into one gesture.

The systematic differences found in NSs from typologically different languages have led Slobin to conclude that in acquiring their native language, children learn particular ways of thinking for speaking, that is, they learn “to attend to particular aspects of experience and to relate them verbally in ways that are characteristic of that language” (Berman & Slobin, 1994, p. 611). In other words, each language trains its NSs to pay online attention to particular details of events when talking about them.

Thinking for Speaking in L2 Acquisition

Slobin’s TFS hypothesis has important implications for adult L2 acquisition. In such a perspective, learning another language entails learning another way of thinking for speaking (Stam, 1998; Cadierno, 2004, 2008), that is, learning the particular verbalized orientation to experience encoded in the grammatical resources of the L2. With respect to motion events, this involves (a) learning which particular details of a motion event must be attended to in the input and expressed in the L2 (e.g., online attention to trajectories vs. static descriptions, and varying online attention to manner of motion); and (b) learning how the semantic components of a motion event (e.g., path and manner) are mapped into L2 surface forms.

In the last few years, research into TFS and L2 acquisition has addressed two main research questions, namely, whether and to what extent adult language learners are able to learn the appropriate L2 TFS patterns, and whether and to what extent this learning is influenced by the specific verbalized orientation of their L1. Empirical work has predominantly focused on the expression of motion, but other semantic domains such as temporality and aspect (e.g., von Stutterheim, 2003), definiteness (e.g., Ekiert, 2010; Han, 2010), and plurality (e.g., Han, 2010) have been examined as well.

The results of this research provide a complex picture, which can be summarized in three interrelated points. First, adult language learners can develop appropriate L2 TFS patterns over time, but this development does not necessarily affect all aspects of a motion event equally (e.g., expression of manner vs. path). That is, within individual learners, some aspects become target-like, whereas others reflect the influence of the learners’ L1 TFS patterns. Second, the influence of the L1 TFS patterns can also be seen in the learners’ gesture patterns. And third, the development of appropriate L2 TFS patterns seems to be particularly difficult when it involves expressing new grammatical distinctions, that is, distinctions that are not coded in the learners’ L1.

The first point can be illustrated by the findings of Cadierno (2004) and Cadierno and Ruiz (2006). These studies have shown that intermediate and advanced learners with an L1 S-language (Danish) and an L2 V-language (Spanish) were able to adopt the L2 TFS patterns in relation to some aspects but not others. For example, they were able to express manner of motion in L2 Spanish with the same degree of elaboration as Spanish NSs and learners with typologically similar L1s and L2s, that is, Italian learners of Spanish; and

half of the learners were able to pay appropriate online attention to scene setting and static descriptions when describing motion events in L2 Spanish. Some of the learners, however, showed traces of their L1 TFS patterns. For example, they tended to provide more complex and elaborated path descriptions than Spanish NSs, as evidenced by the use of inaccurate constructions incorporating anomalous path particles (e.g., **El niño fue arriba de una roca* 'The boy went on top of a rock').

The second point has been shown in studies examining speech and gesture about motion events in an L2 (e.g., Özyürek, 2002; Kellerman & van Hoof, 2003; Brown & Gullberg, 2008). This research shows that both speech and gesture reveal L1-based TFS patterns. For example, when speaking in L2 English, beginning and intermediate Turkish NSs tend to express path and manner in separate clauses, and perform separate path and manner gestures.

The third point can be illustrated by recent research conducted on various semantic domains, namely, motion (e.g., Hasko, 2010), definiteness (Ekiert, 2010; Han, 2010), and plurality (Han, 2010). This research shows that advanced language learners experience difficulties in learning to encode semantic distinctions that are obligatory in the L2 but absent in their L1. This is the case with the obligatory marking of unidirectionality versus non-unidirectionality in L2 Russian by L1 English speakers (e.g., *I'm walking down Gorky Street* [unidirectional] vs. *I'm walking up and down familiar backstreets in my favorite city center* [non-unidirectional]), the appropriate use of L2 English articles by learners of non-article languages such as Polish and Chinese, or the appropriate expression of L2 English plural marking by L1 Chinese speakers. These findings furthermore indicate that acquisitional difficulties can take place not only when the learners' L1 and L2 are typologically different, but also when they are typologically similar (e.g., Polish-speaking learners of L2 English), a result that is congruent with the intra-typological differences being noted in the literature within given types of language (e.g., Ibarretxe-Antuñano, 2004).

The results of the existing research raise several interesting questions for future research, including whether the development of appropriate TFS patterns is possible for all aspects of the L2 (in both speech and gesture); what learning conditions, including L2 pedagogy, can favor such development; and what influence individual learner variables such as language aptitude, memory, or learning motivation may have on this development (Han & Cadierno, 2010).

Third Language Acquisition

JASONE CENOZ

Is it the same to acquire a second language or a third language? Does the second language play a role in third language acquisition? Are we more expert learners if we have already learned a second language? These are fascinating questions taking into account that multilingualism is spread all over the world. This entry discusses the issues examined in third language acquisition research in order to answer these questions. The entry has three sections. In the first section the scope and focus of this research area are defined. The second section gives an idea of the different situations in which a third language or an additional language is learned. In the third section some of the main findings are discussed.

The Scope of Third Language Acquisition

“Third language acquisition” (TLA) has received a lot of attention in the last years but its definition is not an easy task. TLA refers to the acquisition of a language that is different from the first and the second and is acquired after them. The use of the term TLA highlights that there are differences between acquiring a second and a third language and it is a reaction against the use of the term “second language acquisition” (SLA) as a general term for the acquisition of any language other than the first. The term TLA is increasingly used but its scope is not always clearly defined. It can refer to the language chronologically acquired after the second or to any language acquired after the second language. The use of TLA for a fourth, fifth, or sixth language is related to the idea that there are important differences between SLA and TLA but probably not between TLA and the acquisition of additional languages. When several languages are involved, it is sometimes difficult to identify an order because besides chronological order there can be different levels of proficiency in the languages, simultaneous acquisition or intermittent acquisition when the process of acquiring a language takes place in different periods in life (Hammarberg, 2009). One possibility to solve this problem is to refer to “the acquisition of third or additional languages” or even to “the acquisition of additional languages.”

Why is the acquisition of a third (or additional language) different from SLA? The main differences in the process are that third language learners have the experience of acquiring a second language and that they also have some degree of communicative competence in the second language and not only in the first language. Learners of a third or additional language have a larger linguistic repertoire at their disposal and can use this repertoire as a resource when they have limitations in the target language. They can also code switch and code mix to express their communication intent better. TLA research focuses on these differences and highlights the importance of taking learners’ prior experience and competence in different languages into consideration in order to provide an accurate account of the language acquisition process. Third language learners could progress faster because they are experienced language learners but they may also follow a different route than SLA learners because of this previous experience and also because they have access to two linguistic and communicative systems. It has been proposed that the largest qualitative differences can be found between SLA and TLA rather than between the acquisition of a

2 THIRD LANGUAGE ACQUISITION

third and additional languages (Hufeisen, 2004, p. 8). However, more research is needed to confirm this hypothesis.

SLA and TLA also have a lot in common, both theoretically and in terms of research methodologies, but research on TLA is more complex because apart from all the factors and processes involved in SLA, TLA entails some specific characteristics.

Diversity of Third Language Acquisition

TLA is common for many people all over the world. It is more common in bilingual and multilingual contexts where two or more languages are used and a foreign language is taught at school. This is the case of some European regions where a minority language is used (Catalonia, Basque Country, Friesland, Wales) along with the state language and English, French, or other languages are learned as third languages. TLA is also common in the case of immigrant children who speak their first language at home but learn the language of the host country and a foreign language at school. This situation can be found in Western Europe and countries such as the United States, Canada, Australia, and New Zealand where immigrants speak their first languages at home, learn the language of the host country and in the case of schoolchildren additional languages as part of their education. TLA also takes place in areas where multilingualism is part of everyday life and people use different family and tribal languages plus a lingua franca, a national language, or both. There are many other situations in which individuals need to communicate in three languages for other reasons, professional or not.

TLA is potentially more diverse than SLA. The sociolinguistic and educational contexts in which the different languages acquired are potentially more diverse than those involved in SLA. For example, the second language can be used at school or in the community and the third language can be a foreign language (i.e., English L2 and French L3 for a Chinese schoolchild in England) or both the second and third language can be used at school and in the community (i.e., English L2 and Welsh L3 for a Chinese speaker in Wales) or both the L2 and the L3 can be foreign languages taught at school. There can be differences regarding the status of the languages at school, as school subjects or languages of instruction. There can also be diversity regarding linguistic distance between the first, second, and third languages. When more than three languages are involved, more diversity can be found in the acquisition contexts. For example Todeva and Cenoz (2009) list 32 different possible acquisition orders involving combinations of seven different languages that are acquired simultaneously or consecutively. They explain that they only focus on chronological order but that diversity can be related to many other factors related to the dynamic nature of multilingualism such as attrition or the relearning of languages.

The study of TLA has received considerable attention lately and there is a specific journal devoted to TLA and multilingualism, *The International Journal of Multilingualism* (Routledge), and the bi-annual conference on "Third Language Acquisition and Multilingualism." Research on TLA focuses on the specific characteristics of this process and covers linguistic, psycholinguistic, sociolinguistic, and educational issues (see for example Flynn, Foley, & Vinnitskaya, 2004; Safont, 2005; Jessner, 2006; De Angelis, 2007; Cenoz, 2009; Leung, 2009; Wrembel, Gut & Mehlhorn, 2010).

Main Trends in Third Language Acquisition Research

Research on TLA has focused on different areas but two have received considerable attention: the effect of bilingualism on TLA and crosslinguistic influence.

When analyzing the differences between second and third language learning one of the main questions is to see whether bilingualism has an effect on TLA. Most studies on the effect of bilingualism confirm that bilinguals, being more experienced language learners or language users in the case of early bilingualism, have advantages over monolinguals when acquiring additional languages. The results concerning tests of general proficiency indicate that bilinguals progress faster than monolinguals particularly when bilinguals have acquired literacy skills in both their languages. For example, research on TLA in the Basque Country, Catalonia, Canada, and the United States has reported that bilingual learners obtained higher scores than their monolingual counterparts in the acquisition of English or French (see Thomas, 1988; Bild & Swain, 1989; Sanz, 2000; Cenoz, 2009). These advantages have been associated with more developed learning strategies and enhanced metalinguistic awareness (see Jessner, 2006; Kemp, 2007). In a narrative about his process of becoming multilingual, Kamanga (2009, p. 121) confirms these advantages:

I can say that learning languages has become easier with every language that I have added to my repertoire. The more languages I know, the more linguistic information I have as a resource to additional languages.

In general terms, the advantages of bilingualism in TLA are more evident when the L2 and the L3 are closely related such as Spanish and Italian. However, bilingualism is not the only factor involved in TLA and in some cases differences in socioeconomic and socio-educational status have an important influence. For example, in a study comparing L3 learners who were immigrant in the Netherlands and Dutch schoolchildren learning English as an L2, Van Gelderen et al. (2003) found no advantages related to TLA.

Another main area of research in TLA is to analyze the differential roles of previously acquired languages on the acquisition of the target language. Research has proved that learners are influenced by both their L1 and L2 when learning a L3. Research on crosslinguistic influence in TLA has tried to identify the factors that are more influential (Ringbom, 2007; De Angelis, 2007; Hammarberg, 2009). In the case of the lexicon, research indicates that speakers borrow more terms from the language which is typologically closer to the target language. The effect of proficiency in the L2 and the L3 has also been analyzed and learners have been found to borrow more terms from both the L1 and L2 in the first stages of language acquisition. The influence of the L2 can be found even when proficiency in this L2 is not high. Another factor that can potentially affect crosslinguistic influence is “recency” and learners are more likely to borrow from a language they actively use than from other languages they may know but do not use. Regarding the relative weight of the L1 versus the L2 as a source language in crosslinguistic influence, the so-called “foreign language effect” (Meisel, 1983) or also “L2 status factor” that favors the L2 as a preferred source of borrowing has been proposed (Hammarberg, 2009). However, it is difficult to isolate the effect of the different factors so as to predict more accurately the roles of the L1 and L2 in different situations of TLA because of the great diversity of TLA situations and the interactions among these factors (see, for example, Wrembel et al., 2010).

Final Remarks

Research on TLA shows that there are, indeed, some differences between SLA and TLA and that these differences cannot be ignored when conducting research on the acquisition of different languages. It is necessary to consider the learner’s whole linguistic repertoire and to be aware of the possible influence of his/her prior linguistic knowledge and prior experience as a learner on the acquisition of the target language. It is also important to

4 THIRD LANGUAGE ACQUISITION

take into account that TLA research can be informed by SLA research because these two processes have a lot in common. TLA research has developed in the last years but it is still in its infancy. It is necessary to specify more accurately the process of acquiring third languages and explore the specific qualitative differences between SLA and TLA in the route followed by learners. Another important issue is to analyze the differences between TLA and the acquisition of additional languages in order to confirm or reject the hypothesis that the main differences are between SLA and TLA. From a more applied perspective it could be very useful to identify the way that bilinguals can benefit more from their previous experience as language learners in multilingual educational programs.

Tiersma, Peter

BLAKE STEPHEN HOWALD

Peter Meijes Tiersma (1952–) is a linguist and lawyer who is Professor of Law and Honorable William Matthew Byrne, Jr. Chair at Loyola Law School in Los Angeles, California. Tiersma's research and scholarship focuses on numerous types of language in the legal system from a linguistic science perspective, typically drawing on theoretical constructs in historical linguistics, discourse analysis and pragmatics (e.g., speech act theory, Austin, 1962; and implicature, Grice, 1975). For example, Tiersma's *Legal Language* (1999) explores the origins of legal language from the early Anglo-Saxons, through the Norman Conquest, to present day forms (e.g., statutes, testimony, contracts, judicial opinions, etc.) from the perspective of both linguistic and jurisprudential theory and practice. The relevance of this work, which expands the early work of Mellinkoff (1963), stems from the fact that, in a given legal system, there is often a disconnect between the structure and meaning of written laws and the application of those written laws to factual scenarios in the real world, potentially leading to incongruous results. Linguists have sought to correct this disconnect by highlighting the need to understand the history of a given language and basic ideas in linguistics (with an eye toward making intelligent reforms—e.g., the plain language movement). Tiersma also tackles these issues in the face of modern-day computer technology in *Parchment, Paper, Pixels: Law and the Technologies of Communication* (2010).

Closely associated with this general research on the nature of legal language is Tiersma's focus on the language and comprehensibility of jury instructions. In the US legal system, jury instructions are typically written in a complex legal style that can be difficult to understand. However, jury instructions serve as guidance to individuals tasked with determining whether or not a party to litigation is guilty or liable and what punishment may follow. Given the importance of such a task, confusion, language-based or otherwise, should be avoided. Tiersma convincingly argues for clarity and comprehensibility of jury instructions in several articles (e.g., Tiersma, 2001; Tiersma & Curtis, 2008) and has advised numerous jurisdictions on how to better structure and draft jury instructions (Tiersma is a member of the California Judicial Council Advisory Committee on Criminal (2005–present) and Civil (2003–present) Jury Instructions).

In addition to jury instructions and general issues in language and law, Tiersma has also contributed to linguistic analyses of particular language-based legal issues such as defamation (Tiersma, 1987), perjury (Tiersma, 2004) (known as *language crimes*, following Shuy, 1993), and product warnings (Tiersma, 2002). These topics typically fall under what is known as *forensic linguistics*—where language, and the linguistic analysis thereof, is evidence in a given legal proceeding. Further (teamed up with Larry Solan—a linguist and lawyer from Brooklyn Law School), Tiersma has contributed to policy-level issues in forensic linguistics (e.g., the legal system's response to linguistics and linguists' conduct in legal proceedings); including authorship analysis (Solan & Tiersma, 2004), voice analysis (Solan & Tiersma, 2003), and linguistic testimony in general (Tiersma & Solan, 2002). Many of these insights are consolidated in *Speaking of Crime: The Language of Criminal Justice*, which introduces and analyzes multiple applications of linguistics in criminal law settings (Solan & Tiersma, 2005). Like any forensic science, understanding the application of linguistics in the legal system requires an attention to the rules and procedures that govern

the intersection between science and law. *Speaking of Crime* provides a concise discussion of the issues that linguistic science faces in criminal law, the history of its application, and the key legal doctrine implicated.

Tiersma's linguistic training began as a German Studies major at Stanford University where he graduated with a BA, Phi Beta Kappa. After graduating, and teaching English for a year in the Netherlands, he entered the PhD program in linguistics at the University of California at San Diego. Tiersma focused on phonology and historical linguistics with particular emphasis on the Frisian language (Frisian, of the "Western" variety, is spoken in the Friesland region of the Netherlands. The "Northern" and "Eastern" varieties are spoken in Germany—all varieties are a distinct language). Tiersma received a Fulbright Fellowship to conduct fieldwork in the Netherlands—ultimately serving as the empirical basis for his dissertation on phonological theory. In the years following his PhD, he lectured at the University of California at San Diego and the Miami University of Ohio and continued to work on Frisian, including the writing of a reference grammar. Tiersma then shifted to a legal career, which began at the University of California, Berkeley, law school where he was an associate editor of the *California Law Review*. After earning a JD, Order of the Coif, Tiersma clerked for Justice Stanley Mosk of the California Supreme Court and worked as a litigation attorney in several law firms in California.

Tiersma is active in the language and law community in both academic linguistic and legal organizations. He was president of the International Association of Forensic Linguistics (IAFL) from 2005 to 2007, and has also served on the Committee of Social and Political Concerns, Linguistic Society of America (2006–9) and the Panel of Academic Consultants for the 8th Edition of Black's Law Dictionary (2004). He is a member of the editorial board of the *Journal of Speech, Language, and Law* (2004–present) and an organizer (along with Larry Solan and Dieter Stein of Heinrich-Heine-Universität, Germany) and founding member of the International Language and Law Association (ILLA).

Time Series

J. DEAN MELLOW

Research Purposes

The time-series design (TSD) allows applied linguists to investigate two issues: (a) the nature of language use or acquisition over time; and (b) the effect of a specific variable or session of learning on that use or acquisition. The time period of investigation could be seconds and milliseconds, as in applied phonetics research that measures vocal-fold vibrations (e.g., Mergell, Herzel, & Titze, 2000) and spoken discourse research that measures stages in speech planning and production (e.g., Roberts & Kirsner, 2000). This entry focuses on the study of language use and development across days and weeks and in response to particular sessions of instruction.

To investigate development over time, researchers typically choose between longitudinal case studies and cross-sectional studies. In a longitudinal case-study design, researchers elicit parallel samples of language on a regular basis (e.g., once per week or month) over a period of months or years and are able to validly investigate the temporal path of language development. That path may include increases in accuracy and range of use, as well as restructuring of a learner's interlanguage system, which may be revealed by temporary decreases in accuracy (i.e., U-shaped development). In a cross-sectional design, researchers study the language used by learners at different proficiency levels, as determined by factors such as age, number of language courses completed, length of residence in a culture with the new language, or score on a general proficiency test. Researchers infer that these different learners validly represent sequential stages in the acquisition process. Of these two options, the TSD utilizes longitudinal sampling of language use.

To investigate the effect of a specific session of learning, researchers frequently use a pretest–posttest design with a treatment group of learners and a control group. By comparing the posttest changes in the treatment group to those of the control group, researchers are able to assess the effect of a learning event. Researchers control for alternative variables that could cause changes (e.g., learning opportunities outside of the classroom, aspects of aptitude or motivation) by randomly placing learners in each group and by using relatively large groups of learners. The TSD is an alternative for investigating the effects of a learning event. By collecting a number of uses of language for an individual learner before the learning event, a comparison of pretest and posttest scores can reveal whether the developmental patterns in language use were affected by the learning event. However, the results of one case study cannot be generalized to other learners.

TSDs have not been frequently used in applied linguistics research, often because of the difficulty in collecting consistent samples of language over an extended period of time. Participating learners often have life circumstances (such as moving away from the research location) that inhibit regular, long-term attendance at data-collection sessions. To encourage the use of TSDs by applied linguists, an example of a relatively practical, simple design is provided to illustrate some of the key design features. These key features include: establishing sufficient internal validity (confidence that causality has been demonstrated) through sufficient numbers of pretest and posttest scores, assessing the effect of a developmental trend on the interpretation of subsequent acquisition, and assessing the effect of variation

on the interpretation of development (for additional discussion, see Mellow, Reeder, & Forster, 1996).

Example Study

An example of a TSD is illustrated in Figure 1. During a 201 day period, a 12-year-old Spanish learner of English (pseudonym Ana) wrote narratives that explained 15 different wordless picture books (for additional discussion, see Mellow, 2008). Ana had moved to an English-speaking country just prior to the beginning of the study. She began the study with moderate receptive abilities, but more limited productive abilities. During the period of the study, she attended English language schooling for six hours each day. For a four-week period during the study, Ana wrote her own story (*Laura and her friends go to the zoo*). Her mother (pseudonym Sinthya, an EFL teacher) gave Ana feedback on a series of drafts that Ana wrote. One issue that Sinthya suggested was for Ana to avoid the exact repetition of words and instead to use a more varied and precise vocabulary. The TSD allows us to investigate whether Sinthya’s process writing instruction resulted in changes in Ana’s word use in her narratives. Figure 1 shows the number of different types (not tokens or instances) of nouns that were the heads of noun phrases in the first 200 words of each text

Figure 1 Scatterplot of scores, a preinstruction (PreI) regression line projected into the postinstruction (PostI) phase, and a parallel line two standard error of estimate (2 SEE) units above the PreI regression line for the number of types of head nouns (Noun) within the first 200 words of each text written during the 201 days of the study

Note: Michele Akçar and Maria Clemencia Gonzalez assisted with this data collection and analysis.

that Ana wrote. The coding was lemmatized: inflectional variants (e.g., *book*, *books*) were counted as just one type of noun.

An examination of the scatterplot of scores during the preinstruction (PreI) phase (day 1 to day 126) shows that Ana used between 11 and 25 different types of nouns in the nine stories that she wrote, averaging 17.2 different types. During the postinstruction (PostI) phase (day 157 to day 201), Ana used between 22 and 27 different types of nouns in four stories, averaging 24.5. When a TSD has this small number of data points (nine PreI scores, four PostI scores), a visual examination of the scatterplot is often the best approach for interpreting the results. The PostI phase has two scores that are higher than any of the scores during the PreI phase and two other scores that are comparable to the highest PreI scores. This visual examination suggests that the instruction was effective and encouraged Ana to use consistently a variety of types of nouns. By visually comparing nine PreI scores to four PostI scores, this TSD allows a researcher to be fairly confident that the high scores were due to the instruction and not to another factor. In other words, the internal validity is relatively high.

Beyond a visual inspection of the scatterplot, the TSD allows additional analytical procedures that can increase the precision of the interpretation of the results. A moderate number of PreI datapoints allows researchers to assess the developmental trend before instruction and the amount of variation that is typical of the learner's use on this type of task. To characterize the trend and variation in the PreI data, a regression line has been plotted through the scores and extended into the PostI phase. The PostI results in relation to the projected regression line must be interpreted with caution. Specifically, the sample size ($N = 9$) in the PreI phase is quite small in order to validly use a regression line (see Tabachnick & Fidell, 1989, p. 129). In addition, the regression line has been projected outside of the PreI data period and the estimates of variation and error are increasingly less accurate when the scores are farther away from the center of the PreI phase for which the regression line was computed (e.g., Gottman & Glass, 1978, p. 204; Fleming & Nellis, 1994, p. 248). For these reasons, the term *statistically significant* cannot be used to describe large pretest–posttest differences in scores that are interpreted through the use of this regression line. A term such as *noteworthy* is more appropriate.

An examination of the PreI regression line in Figure 1 shows that there was a trend in which Ana used fewer types of nouns in her later stories than in her earlier stories. This trend may be due to an increase in her use of other types of words (not illustrated here) as her writing ability improved and her sentences became more complex. If this downward trend had continued, Ana would have only used 10 to 15 types of nouns during the PostI phase, even though the average during the PreI phase was 17.2 types. Thus, one of the key features of the TSD is that developmental changes over time may be observed and used to interpret data.

An examination of the PreI data points also shows that Ana varied considerably in the number of types of nouns that she used (between 11 and 25). The amount of variation can be seen by noting that six of the data points are quite far away from the regression line. The computation of a regression line produces standard error of estimate (SEE) units (i.e., the variation or error not accounted for by the regression line). If data are distributed normally, approximately 95 percent of the scores fall within two SEE units of the regression line (see Woods, Fletcher, & Hughes, 1986, pp. 101–3, 231). To show the amount of variation in the PreI phase more precisely, a line has been drawn two SEE units above the regression line and then extended into the PostI phase. In combination with the downward slope of the regression line, the 2 SEE line within the PostI phase confirms the general visual analysis of the scatterplot. All four PostI scores are above the 2 SEE line. The increase in the number of types of nouns after instruction was noteworthy. In addition, the amount of variation

in the PostI scores appears to be less than the PreI variation. Thus, another strength of the TSD is that variation in language use can be observed and used to interpret the data.

Additional Design and Analysis Possibilities

A TSD can be elaborated by increasing the number of data points per learner or by increasing the number of learners or both. If a large number of data points per learner is obtained, a variety of mathematical models can be used to interpret the data. Many of these analyses have been utilized within a dynamic systems approach to development (e.g., van Geert & Steenbeek, 2005).

The systematic inclusion of multiple learners can increase the internal validity of a design. If several learners randomly receive the experimental treatment session at different points in time, then these replications of the single-case design are called a multiple-baseline design (e.g., Mellow et al., 1996). Specific statistical tests, such as Revusky's R_n , have been developed to interpret changes in scores in multiple-baseline designs (e.g., Revusky, 1967; Kazdin, 1982). In another type of design with multiple learners, Ishida (2004) utilized a TSD that combined scores for pretest, treatment, and posttest periods and used a repeated-measures analysis of variance, in conjunction with a Helmert analysis, the Pearson product-moment correlation coefficient, and implicational scale analyses.

In order to investigate and interpret the effects of instruction, the use of TSDs can be informed by fundamental issues in measurement and in theories of acquisition. Prompted production tasks, such as narrative descriptions of wordless picture books, elicit extended discourse that is relatively authentic and communicative (i.e., has high construct validity). However, parallel tasks need to be carefully chosen or created and then presented in a random order. One threat to the internal validity of the study in Figure 1 is that the final four picture books were all created by the same illustrator. It is possible that the nature of those pictures elicited more nouns than did books by other illustrators.

In addition to variation in language use due to differences in elicitation tasks, other aspects of variation result because language is not a fixed system but instead is a dynamic system that changes over time and is used differently in different contexts (e.g., Larsen-Freeman, 2006). The language use of learners exhibits an especially high degree of variability. Larsen-Freeman (2006, p. 593) argued that this variation "should not be dismissed as measurement error." When the effects of instruction are assessed with measures of central tendency (such as averages or means), high amounts of variation often lead to differences that are not statistically significant. However, current theories of acquisition, such as emergentism and dynamic systems theory (e.g., Ellis & Larsen-Freeman, 2006; de Bot, Lowie, & Verspoor, 2007), focus on both variation and central tendency, necessitating the types of quasi-experimental designs, such as TSDs, that can fully investigate the nature of language acquisition and use.

This discussion has illustrated that the TSD is a type of quantitative research that involves quantification of data, numerical analyses, and the assessment of causal relationships between variables (Mackey & Gass, 2005, pp. 2, 137–8). However, a TSD may also have characteristics that are typical of qualitative research, including a smaller number of research participants that allows careful and detailed descriptions of naturalistic and communicative language use, as well as analytic categories and hypotheses that emerge from these rich data (Mackey & Gass, 2005, pp. 2, 162–4). This combination of characteristics reveals that TSDs are especially fruitful as applied linguistics research that can complement other types of quantitative and qualitative studies.

I would like to thank Michele Akçar and Maria Clemencia Gonzalez who assisted with data collection and analysis.

Traditional Approaches to Monolingual Lexicography

THOMAS KLEIN

Lexicography is properly the practice of writing dictionaries, and more generally of compiling and recording information about the lexicon of a language and presenting it effectively to native or non-native speakers and learners of the language. This entry will focus on traditional *monolingual* lexicography, which presents and defines the words of a language using only other words of that language, as opposed to *bilingual* lexicography, which works between two languages; it thus presupposes at least some base knowledge of that language. The entry will begin with a brief overview of traditional monolingual lexicography and its history, move to the structural challenges lexicographers must address, and finally consider what the future may hold for the field and for dictionaries.

Traditional Lexicography and the “Prototypical” Dictionary

The term “traditional lexicography” refers to those approaches to dictionary writing which have been practiced since the inception of monolingual lexicography, even as they have been shaped both by discoveries in linguistics and by commercial concerns. Traditional lexicography is generally associated with books (although electronic dictionaries are rapidly taking their place) and, as books, dictionaries have a rich history and occupy a central position in the literate culture of many societies, if at times a problematic one, not least for their perceived role in prescribing usage, that is, of setting standards in the use of language. At other moments, dictionaries have a descriptive function, that is, of recording and cataloguing language, and may be a source of great cultural pride. They might be known by such terms as lexicons, word lists, or glossaries, and be manifested in such forms as dictionaries of synonyms (thesauri), technical dictionaries, dialect dictionaries, collocation dictionaries, or learners’ dictionaries. However, this entry will focus on what many readers may consider the “prototypical” dictionary: the alphabetical monolingual all-purpose dictionary (Van Sterkenburg, 2003, p. 3).

Certainly, the general public’s understanding of dictionaries and lexicography often differs considerably from that of the lexicographers themselves, who are faced with practical questions of how to organize their dictionaries, gather information, decide what needs to be included (and excluded), and present that information in a helpful way. Since the 1960s, lexicography has evolved to become an object of academic study in its own right: The literature about lexicography is sometimes referred to as “metalexicography.” Its relationship to applied and theoretical linguistics remains a subject of debate, some commentators regarding it as a subfield of applied linguistics, others regarding it as a distinct discipline (Tarp, 2008; De Schryver, 2009). Both Béjoint (2010, chap. 10) and Atkins and Rundell (2008, p. 4) deny the status of lexicography as a theory (see also Bogaards, 2010). Thus, while modern lexicography certainly draws upon many of the findings of both theoretical and applied linguistics (and often employs sophisticated technology), some have wondered whether it is not more of an art than a science. It seems likely that many of those people engaged in the actual practice of lexicography would say that it involves quite a bit of both.

History and Development of Monolingual Dictionaries

A review of the history of lexicography is useful because, in many ways, the problems faced by past lexicographers are ones still faced by those working in the field today. The first practice of lexicography may go as far back as 2600 BC when the Akkadians wrote thematic summaries of the Sumerian language on clay tablets (Van Sterkenburg, 2003, p. 8). While the Indian, Chinese, and Arabic cultures all practiced forms of monolingual lexicography one or more millennia ago (Haywood, 2003; Katre, 2003; Xue, 2003), in Western Europe lexicography was at first wholly bilingual, and appeared in the form of medieval manuscript glosses, whereby vernacular equivalents were written above each word in the Latin or Greek text for the benefit of the text's non-native readers; these glosses might subsequently be assembled into glossaries, organized topically, to facilitate second language learning (Hüllen, 1999). The first books we might recognize as dictionaries proper appeared in the European Renaissance and were bi- and even multilingual (polyglot); for instance, Berloement's 1586 *Colloquia et dictionarium* presented columns of equivalent Flemish, English, German, Latin, Italian, Spanish, and French words, the first column organized in rough alphabetical order.

For many native speakers of earlier stages of English, the need for a monolingual dictionary might not have been immediately obvious until the European Renaissance. For a speaker of Old English, for instance, with its relative absence of borrowed vocabulary, most words would be semantically transparent, even those elaborately compounded and affixed. With the dramatic influx into English of Latin-derived and other foreign terms from the 16th century onward, this was no longer the case. At the same time there arose a general anxiety about the language, especially regarding what words properly belonged to it. Thus in 1582 Mulcaster catalogued but did not define 8,000 English words, while Cawdry's 1604 *A Table Alphabeticall* is often regarded as the first monolingual English dictionary. Cawdry's title page is revealing:

A Table Alphabeticall, Conteyning and teaching the true writing, and understanding of hard usuall English wordes, borrowed from the Hebrew, Greeke, Latine, or French. &c. With the interpretation thereof by plaine English words, gathered for the benefit & helpe of Ladies, Gentlewomen, or any other Unskilfull Persons.

Cawdry's dictionary was thus what is known as a "hard-word" dictionary, and his basic purpose is not unlike that of lexicographers today: According to the title page, readers should "more easilie and better understand many . . . wordes, . . . and also be made able to use the same aptly themselves." His definitions were simple semantic equivalents (for instance, *ebulliated* is defined as "boyled"). For the following 50 years, dictionaries, both in England and on the European continent, focused essentially on hard words; however, perhaps to increase the value of their product, lexicographers began to introduce non-linguistic information, as we see for instance in this entry from Blount's 1656 dictionary defining *Coffa* (coffee):

A kind of drink among the Turks and Persians (and of late introduced among us) which is black, thick and bitter, distained from Berries of that . . . name, thought good and very wholesome: they say it expels melancholy, purges choler, begets mirth, and an excellent concoction.

This sort of entry introduced a debate which continues today regarding what kind of information dictionaries should include: Should they involve just words and definitions, or should they include cultural and encyclopedic information?

From the later 17th century onward, new dictionaries entered a fiercely competitive market, compelling editors to include ever more words and definitions and such non-lexical information as place-names and the names of mythical figures. Kersey's 1702 dictionary was one of the first dictionaries in English to include common words. Specialized dictionaries were also introduced, focusing on etymology, spelling, pronunciation, and "cant" or slang, among other topics.

In the midst of all this activity, however, Johnson's 1755 dictionary stands out as a particularly important achievement for monolingual lexicography. Though not all-inclusive, Johnson's work was quite comprehensive. In addition to including clear indications of a word's part of speech and its derivation, he established what is still essentially the modern lexicographical pattern for defining and ordering distinct word senses and, though working from self-selected examples from "the best writers," prefigured the corpus-based approach to lexicographical definition, as this example shows:

ECO'NOMIC. / ECO'NOMICAL. *adj.* [from *economy*.]

1. Pertaining to the regulation of an household.

Her quick'ning power in ev'ry living part,
Doth as a nurse, or a mother serve;
And doth employ her *economick* art,
And busy care, her household to preserve. *Davies.*

2. Frugal.

Some are so plainly *economical*, as even to desire that the seat be well watered, and well fuelled. *Wotton's Architect.*

In the words of one scholar, the strength of this dictionary lies in the way that "Johnson strips away both Latin and source references to focus exclusively on what the word means and denotes" (Lancashire, 2005, p. 158); likewise, Johnson's notes on usage provide "a rich and elaborate set of information" in contrast to earlier writers (Barnbrook, 2005, p. 198).

Elsewhere and later, in the USA, the commercial and cultural need for a "universal" dictionary (i.e., one including all words in the language, or as near to that as possible) was answered by Webster's 1828 *American Dictionary of the English Language*, which included the largest number of entries of any dictionary up to that point, and used American spellings and pronunciations. Curiously, while Webster was critical of Johnson's at times idiosyncratic and "vulgar" definitions, he retained many of them with only slight modifications, reflecting a time-honored practice among lexicographers to draw heavily upon previous work (even to the extent of plagiarizing). Nonetheless, Webster remains a household name representing the authority of the dictionary in general.

The *Oxford English Dictionary* (OED), which was begun in the mid-19th century, first completed in 1933, but since then more or less continually updated, continues to stand as a major lexicographical achievement. Its goal has been to record all words entering the English language since the Old English period and to track their development using illustrative quotations from extant works, following Johnson's example. However, unlike Johnson's dictionary, the quotations were originally generated by a volunteer corps of readers who scanned historical and recent works for illustrative uses of words and then wrote their examples on slips of paper and posted these to the editorial team, for many decades led by the charismatic James Augustus Murray. The dictionary broke ground not only by its scope but also by its attempt to be essentially descriptive in nature, though occasionally violating this principle (Brewer, 2007). Now available online, it offers itself as a clearing house both for new words and for new uses of words in English; editors are thus continually faced with the practical problem of when to accord a word official status.

Historical dictionaries for other languages have followed the *OED*, including the *Grande dizionario della lingua italiana* for Italian and the *Trésor de la langue française informatisée* for French, although these have tended to draw their examples chiefly from canonized authors, thus having a strongly prescriptive aspect (Beltrami & Fornara, 2004; Baider, 2007). Since the 1960s, however, lexicography has been deeply influenced by corpus linguistics so that most new dictionaries are built from illustrations drawn from corpora, following Sinclair's belief that "natural language use constitute[s] the best source of linguistic evidence" (Krishnamurthy, 2008, p. 231). As Rundell (2002, p. 140) writes, the "corpus revolution" has advanced to such a degree that it is now generally assumed that "corpora of naturally-occurring text [will] provide the primary data source for all good dictionaries." In theory, this means that dictionaries will be derived from objective evidence; in practice, the editor's intuitions about the language are usually still important.

Findings in linguistics and applied linguistics have influenced, and been influenced by, modern lexicography in other ways. Since the definition of words involves dealing with their form, meaning, and function, those branches of applied and theoretical linguistics that treat phonetics, phonology, morphology, semantics, syntax, collocation, and pragmatics (among other topics) are all potentially relevant to lexicography. Svensén (2009, p. 3) remarks, "there is almost general agreement that linguistics forms an import basis for [modern] lexicographic work, and conversely, that lexicography and its products have made considerable contributions to linguistic research." Thus, work in frame semantics, which asserts that word meanings can only be explained and understood in terms of the conceptual structures, beliefs, and cultural practices of a given speech community, and in lexical collocations, which governs the contexts in which words appear, may well have been influenced by the development of learners' dictionaries, such as the *Collins COBUILD English Dictionary*, which seeks to provide elaborate intra- and extralinguistic contextual illustrations of particular words.

Structuring the Dictionary

The practice of lexicography involves a number of common concerns beyond those mentioned above. Among these are the problems of how lexicography's final product will be structured, how the words or *lexemes* (the more precise linguistic term for the basic abstract unit underlying grammatical and phonological variants, such as *see*, *sees*, *seeing*, *saw*, *seen*) will be presented, and especially how their meanings will be defined.

Lexicographers generally mark a distinction between a dictionary's overall structure and organization—its *macrostructure*—and the structure and presentation of its individual entries or articles—its *microstructure*. Both categories may be shaped in particular ways to reflect the needs of users, and by the same token they may well determine how effective a particular dictionary is.

The macrostructure of the typical dictionary is an alphabetical structure organized around the base form of the words contained within the dictionary. It is difficult to overstate the importance that alphabetization, especially letter-by-letter (that is, alphabetization that continues beyond the first letter of the word), has played historically in the organization of dictionaries; even lexicons of languages like Chinese, whose written form is not based on letters but on logographs, may follow a form of alphabetization (Xue, 2003). While alphabetization has considerable advantages, it may also widely separate semantically or etymologically related words; as Hüllen (1999, p. 11) notes, "*creatine* is placed between *create* and *creation*, *credenza* between *credential* and *credibility*." The macrostructure may also take such forms as a topical or thematic structure, where lexemes are organized into broad areas of human knowledge and experience, each broken into further categories and

subcategories. This is indeed the structure of many thesauri, which “help users in finding words or the synonyms and antonyms of words or stylistic variants [and] provide the basic vocabulary within a semantic domain” (p. 15).

The microstructure of each entry in the prototypical dictionary may take different forms and may include different kinds of information; in general, lexicographers aim to follow (but may not always achieve) a consistency of presentation. The base form of the word presented, known as the *headword* or *lemma*, may be followed by such information as an indication of the part of speech, pronunciation, etymology, usage labels, ranked definitions, and usage illustrations among many other features (including pictures). Lexicographic microstructure depends heavily on a hierarchical organization, both in the ordering of elements and in their typographic presentation, the purpose of which “is to assist the user in identifying and distinguishing the different items and in finding them as quickly as possible” (Gouws, 2003, p. 35), as well as determining their relationships. This of course requires the lexicographer to make many judgment calls—for instance, deciding how to distinguish homophonic but etymologically distinct headwords.

Though users go to dictionaries for many different reasons, it is likely that the most common reason is to find a definition of the various meanings of a word. Van der Meer (2006, p. 604) observes that “after centuries of practical lexicography, there is still hardly any consensus on how to divide the semantic space of a lexical item. Nor does theoretical semantics seem to have made any impact with respect to this problem.” Van der Meer argues, against the emphasis on collocation and context, that “speakers normally have a context-free idea of [a lexeme’s] meaning” (p. 608). This echoes Wiggins’s (1971, p. 33) earlier sentiment that “it is a part of the equipment of a mature speaker of a language that he possesses some principles . . . which enable him to invent or ‘cotton onto’ new uses of a word and see their rationale.” It may be said that art enters in here in particular; since the lexicographer must somehow acknowledge this innate ability, “anything that absolutely denies the reader the opportunity to find out the meaning of a word he has looked up is the most serious defect a dictionary can have” (Landau, 2001, p. 157).

Future

Regarding the future of lexicography, there is reason to be both optimistic and cautious. As De Schryver (2009) shows, the field of lexicography as an academic discipline continues to develop apace; as in any other vibrant field, several specialized journals are devoted to it, including the *International Journal of Lexicography* (England), *Dictionaries* (North America), and *Lexikos* (South Africa); other linguistic and philological journals also frequently publish articles with a lexicographic focus.

As for dictionaries themselves, it is clear that in the near future they will continue to provide the same kind of help they always have to users. Learners’ dictionaries for non-native speakers and research in dictionary use represent areas of particularly dynamic development. With global shifts in populations and political power, it is easy to see why. The function of dictionaries as catalogues and archives of language will likewise remain important, especially in the instance of rapidly changing or disappearing languages, even if the audience for such dictionaries remains small or academic. With the rapid development of unique fields of expertise and experience, some form of specialized dictionaries will also continue to be useful.

The transition from print to electronic form of many dictionaries has provided a number of benefits as well as some negatives. For instance, the electronic *OED* allows for easier and specialized searching; more generally, definitions can be retrieved more rapidly, with dictionaries readily available in smartphones and handheld devices. Some users, however,

may feel that something is lost in the transition from print to digital format. Web searches for definitions may yield an overabundance of results, with no clear hierarchy to prioritize them (and sometimes with a surprising absence of the particular definition for which the user is searching). In the absence of a physical, branded book, dictionaries will probably lose both their autonomy and their authority. The form of the electronic dictionary is certainly extremely convenient, but some of the enthusiastic claims initially made for them have not fully delivered on their promise (De Schryver, 2003; Lew & Doroszewska, 2009).

While the user-generated encyclopedia has enjoyed great success in recent years, the same cannot be said generally of attempts to create user-generated dictionaries. At least in the case of English, entries either are inadequate or are simply reproductions of previous print dictionaries. As the creation of the original *OED* demonstrated, while lexicographical content might be generated by non-specialists, the effective arrangement of that content is dependent on the careful work of trained editors. Thus, while a computer can now generate the illustrative quotations for a corpus-based dictionary instantly (and as such is an extremely useful tool), there is no prospect that the painstaking work of an editor can be fully automated (Rundell, 2002). New projects such as OmegaWiki, an attempt to create a “dictionary of all words of all languages” through the efforts of users, have been touted (Meijsson, 2009); like the polyglot dictionaries of the Renaissance, such projects may be more intellectual curiosities than genuinely and consistently useful.

Finally, Tarp (2009) speaks about the current “identity crisis” facing lexicography. This is partly due to the dictionary’s changing status described above; it also arises inevitably from the rapid development of lexicography itself as an academic discipline which has resulted in a separation between theoretical approaches to lexicography and actual practice. It will be interesting to see what the 21st century holds both for the field and for dictionaries; certainly, lexicography will continue to be practiced and relevant, but in what form is anyone’s guess.

Transcribing Multimodal Interaction

HELEN SISSONS

In appreciating what is involved in transcribing multimodal interactions, the researcher must first understand what constitutes multimodal data. A multimodal approach to communication understands that people use a range of modes, not just language, to communicate. They may employ images, gesture, gaze, posture, and so on, and the relationship they form between these modes communicates meaning. Therefore each of the communicative modes used by research subjects during an interaction is analyzable data. When collecting such data, a researcher generally utilizes video- or audio-recorded data collection methods, or both. Then, because transcribing multimodal interactions is time-consuming and complex, the researcher must carefully select representative samples from the raw data before beginning the transcription process.

Background

It is the developments in technology which have allowed researchers to gather multimodal data and afforded them transcription methods which take account of multiple modes. However, it is only relatively recently that researchers have recognized the advantages to understanding that analyzing interactions from the point of view of more than one communicative mode afford.

In the 1990s, Gumperz and Berenz wrote that when people are talking they exchange verbal and nonverbal signals informing them how the conversation is progressing: "Conversing in turn rests on speakers' and listeners' interpretation of verbal and nonverbal signs or contextualization conventions; that is, systems of cues that guide conversational management" (Gumperz & Berenz, 1993, pp. 91–2). They presented a transcription system that focused on speakers' and listeners' use of nonverbal as well as verbal signs to convey and understand information and to maintain what Goffman (e.g., 1963) called "conversational involvement." Common nonverbal actions were described within square brackets. Others researchers too referred to the nonverbal or extralinguistic characteristics of interactions, but spoken language remained the focus (Flewitt, Hample, Hauck, & Lancaster, 2009, p. 41). In 1996 the New London Group, which included Courtney Cazden, James Gee, Gunther Kress, and Allen Luke, began to be interested in multimodality. From their investigations it became clear that in the "new," multimedia, multimodal landscape, researching meanings beyond the purely linguistic was necessary (Jewitt, 2009, p. 19).

In the late 1990s and early 2000s there began an increased focus on multimodality within research and the employment of visual research methods (Scollon, 1998, 2001a, 2001b; Kress, Jewitt, Ogborn, & Tsatsarelis, 2001; Kress & Van Leeuwen, 2001; Van Leeuwen & Jewitt, 2001). However, the new focus brought challenges as to what data to collect and how to represent these novel kinds of data as text.

Multimodal Data Collection

As already mentioned, innovative technologies have provided new tools for data collection, such as digital photography and video- and audio-recording devices. While researchers

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal1219

have recognized that these technologies can create rich data, no one type of data on its own can give a full picture. Norris writes when explaining her long-term ethnographic study of two German women that “as each form of data has its own weakness, a collection of various forms of data allowed triangulation” (Norris, 2011, p. 82). She and most other researchers continue to use interviews, documentation, and field notes alongside the newer tools, merging the resources to enable a fuller analysis. “The combination of ‘new’ and more traditional tools for data collection creates a dynamic constellation of resources, where meanings are produced through the inter-relationships between and within the data sets, permitting the researcher literally and metaphorically to ‘zoom in’ on fine-grained detail and to pan out to gain a broader, socially and culturally situated perspective” (Flewitt et al., 2009, p. 44).

Multimodal Transcription

Having a “constellation of resources” has implications for transcription. In order to present and analyze such diverse data, new kinds of research texts have had to be devised. Given the relative youth of multimodality and the heterogeneous backgrounds of the researchers, it is not surprising that different transcription systems have been devised depending on what the researcher wants to discover and the type of data they have. “No matter which transcription system is used, it is generally well understood that the transcript guides—or even forces—the analyst to a certain interpretation of analysis, which, of course, simultaneously constrains the analyst to a certain interpretation as well” (Norris, 2011, p. 112).

Any transcript necessarily prioritizes some details and omits others altogether (Flewitt et al., 2009, p. 45). The challenge is that the format should accurately exemplify events in a manner that can be clearly understood and that aids the purpose of the research. The transcript system used should also exploit fully and represent fairly the data collected. Therefore the transcription format for static texts such as newspapers is likely to be different from that used for naturally occurring interactions.

Some researchers focusing on the analysis of texts both static and dynamic (O’Halloran, 2004; Baldry & Thibault, 2006; Bateman, 2008; among others) have devised systems for the analysis of these genres. Others, including Norris, are interested in naturally occurring interactions. She presents a system suitable for the analysis of such interactions where gesture, gaze, proximity of the participants, and setting may all provide information which needs to be included in the transcription.

Data Annotation and Analysis Tools

In addition to the systems discussed above, a range of annotation and analysis resources for audiovisual data are now available. These include annotation tools, such as ANVIL, ELAN, EXMARaLDA, MacVisTA, and TASX, which offer an interface set out like a music score rather than an annotated text document format. Hence, when data come from several participants speaking and producing various nonverbal behaviors simultaneously, this sort of layout has the potential to be easier for the researcher and reader. The tools also allow for the importing of other software, such as speech annotation software like Praat and XWaves, and time-stamped files for statistical processing in packages such as Excel. A review of these resources is presented in Rohlffing et al. (2006).

Data analysis software packages such as HyperRESEARCH, NVivo Atlas.ti, MAXqda, QUALRUS, and Transana offer a framework for the organization, coding, searching, and retrieval of data. For a discussion of these see Flewitt et al. (2009) and the Computer Assisted Qualitative Data Analysis (CAQDAS) Web site (<http://caqdas.soc.surrey.ac.uk>).

What Is Transcribed?

Conventionally the focus of research was on language, and the unit of analysis was a turn in speech. In multimodality, however, language is only ever one mode among an ensemble of modes and is not elevated above the others. For multimodal researchers, the unit of analysis can be a visual unit, it can be temporal, or it can be an action. Baldry and Thibault (2006), for instance, use time as a unit of measurement, a unit being one second, while Norris (2004, 2011) uses mediated actions as a unit of analysis, for example a hand gesture or a gaze shift (see below). No matter what the unit, the representation of multiple modes in meaning making results in multimodal transcription being a time-consuming and complex exercise. For an effective transcript that clearly represents how the different modes interact to reveal the meaning of the text or interaction, the researcher or transcriber has to decide how much detail is necessary to fulfill the aims of the research while at the same time keeping the transcript uncluttered enough for a clear reading by an audience.

A number of researchers use columns to represent simultaneous multimodal phenomena (Baldry & Thibault, 2006); still others mix images with verbal transcriptions of speech and descriptions of action to present the interplay of multiple modes. Goodwin (2007) incorporates drawings, video stills, timed pauses, superimposed arrows, and analysis into his transcripts (for a description, see Flewitt et al., 2009, pp. 46–51). One of the more innovative transcription systems is highlighted here: that of Norris. Unlike many researchers who still present their data in written form—that is, the modes are translated into the verbal mode—Norris's transcription is image rich.

A Transcription Case Study

Norris explains that a transcript is a first analysis, which is used for the purposes of further analysis as well as for representation (2011, p. 113). Including images in the verbal transcript, she argues, allows for a more comprehensive analysis of interactions. Her unit of analysis is the mediated action. The smallest of these actions Norris calls the lower-level actions, which may be a gesture, a postural shift, or an utterance. Higher-level actions such as a conversation or presentation are made up of chains of lower-level actions that must be represented on a transcript. “The task of a multimodal transcript is not to analyze the images that are incorporated, but rather to use the images in order to describe the dynamic unfolding of specific moments in time in which the setting and the non-verbal play as much a part as the verbal” (Norris, 2011, p. 111).

For the researcher wishing to use Norris's system, she suggests the production of individual transcripts for each communicative mode—for example, layout, gesture, gaze, proxemics, and spoken language—which could then be collated with the help of time as the reference into what she calls a final multimodal transcript of the site of engagement. She has outlined some conventions for each communicative mode, which are explained in more depth in Norris (2004, 2011).

Spoken Language

Norris bases her transcription of spoken language in part on Tannen's (1984) transcription conventions.

1. Punctuations reflect intonation, not grammar.
2. Brackets show overlap:
 └two voices at once.
3. CAPS indicate emphatic stress.

Figure 1 Intonation patterns in waveform as shown in WaveSurfer

4. Numbers in parentheses () show the length of pauses in seconds.
5. Latching is indicated Z by these brackets.
6. – marks a glottal stop or abrupt cutting off of sound.
7. 0:00.00 indicates the minute, second and millisecond (or frame) of the beginning of an utterance.
8. In order to replicate the intonation patterns as waveforms in the multimodal transcript, each utterance is viewed in an audio program such as PRAAT or Wavesurfer (see Figure 1).

Proxemics

Norris transcribes proxemics (proximity of the participants) as follows:

1. An initial still image shows the distance that the participants are from one another and from relevant objects.
2. A new image shows each change in proxemic behavior by the participants, and the time in minutes and seconds of the image as it appears in the original clip is marked.

Figure 2 Video stills for a multimodal transcript (Sissons, 2011) © Routledge

Posture

The participants' posture is transcribed.

1. An initial still image shows the posture of the participants.
2. A new image shows each postural change by every participant, and the time in minutes and seconds of the image as it appears in the original clip is marked.

Gesture

The participants' gestures are transcribed.

1. The onset or rest position is shown, then the stroke or highest position, and then the retracted or rest position of the gesture, and the highest and lowest position for a beat.
2. Some gestures also show the mid-points of the preparation, retractions, or both. If the gesture includes a post-stroke hold, that is indicated in a separate image.
3. The times of the still images as they appear in the original clip are always marked.

The same is done for the other modes relevant to the interaction. Many modes will overlap, and the researcher uses the timings marked on the screen grabs and in the audio transcript to produce a final transcript which illustrates such overlaps as and when they are important. In the final transcript spoken language has to be reproduced, illustrating intonation patterns, pitch, and volume of the speakers.

It is clear from the timings shown in Figure 2 that the unfolding interaction has been illustrated using images which do not appear at uniform time intervals. This is because of the need to illustrate the modal meaning making as it occurs. Had every fourth image been displayed, for example, meaning would have been missed.

Further, in transcribing each mode separately it becomes clear, Norris notes, that the hierarchy of modes changes during an interaction. At one moment speech and manual gesture will be in the superordinate position, at another gaze and so on. In the example in Figure 2, posture, proxemics, and use of the mediational means (the cleaning tools shown) as well as spoken language are central to the meaning making in the interaction.

Conclusion

The introduction of new technologies has afforded opportunities as well as challenges for researchers wishing to gather and transcribe multimodal data. As yet there is no widely accepted paradigm for the transcription of multiple modes, but it is becoming more recognized that the aim in the analysis is not to prioritize language. Questions, however, still remain for the researcher as to how much complexity can be included in a transcript before readability becomes too impaired.

Transcription

NORBERT DITTMAR

Problem Space

Transcription (from Latin *transcribere*, ‘to transcribe’) means “any graphic representation of selective aspects of speaking and of one or more persons’ behaviour and setting concomitant with speaking” (O’Connell & Kowal, 1995, p. 646). The Latin proverb *verba volant, scripta manent* (“words are fleeting, but written they remain”) reflects the fact that only written discourses were taken as “legitimate” text resources in developed societies before the 20th century. Most of the world’s societies use a coded written alphabet which fits the norms of a standard language and serves as a normative system for any legitimate public communication. It is a code independent of social context and the changing conditions of verbal interactions in situational settings.

Writing and speaking are quite different communicative activities: Oral language use implies social, emotional, and referential proximity (“familiarity”) in dynamic interactions in a specific situational context, whereas written language represents local, referential, and emotional distance in communication (Fiehler, Barden, Elstermann, & Kraft, 2004). Although stenographic representations (Crystal, 1997, p. 382) and standardized protocols in the second half of the 20th century (Dittmar 2008, pp. 24–5) were used as technical tools for the conservation of oral communication, most of the current definitions of transcription are based on *scientific criteria*: The written representation of spoken language should be as authentic as possible, reflecting the “real” communication situation in coding the verbal and nonverbal aspects of communicative exchanges in the most adequate way. The sign repertoire of a transcription system (TS) should represent the oral messages on the basis of analogical observational adequacy (see below on Jefferson’s “eye-dialect” for an inadequate solution). Modern histories of TSs distinguish the development of (a) at the end of the 19th and the beginning of the 20th century, a narrow phonetic system (the International Phonetic Alphabet [IPA]) for representing the sound system of different dialects of a particular language like German, Italian, American English, and so forth, and of different standard languages in the world in order to facilitate language teaching; and (b) a broad transcription of all kinds of communicative genres and styles according to authentic conversational criteria, including prosodic and nonverbal behavior, with an emphasis on the criterion of “good readability.”

Historical Development of Transcription Systems

The first writing systems are documented 3,500 years BC. In order to conserve moral, religious, and legal principles for the sake of authenticity, collective memory, and reliability, humans of different groups and societies developed writing systems of very different forms (pictograms, ideograms, hieroglyphs, and logograms). But besides the codified written standard, many communication communities (tribes, ethnic groups) used only oral ways and varieties of speaking. Anthropological linguists were first motivated in the 19th century to document the whole diversity of human languages in order to compare them.

2 TRANSCRIPTION

The most efficient tool for documentation has been the IPA, first published in 1888; it codes the phonetic equivalents of the particular sounds of all languages worldwide in a universal representation. A phonetic symbol corresponds to an oral version of a sound in real life. Thus the pronunciation of standard German /s/ (phoneme) is realized by the two variants [s] and [z] in oral communication. Wherever the repertoire of phonetic symbols does not render precisely enough the quality of the sound, *diacritics* supply the particular phonetic values. Each phonetic symbol is an abbreviation of the articulatory features of a sound; for example, [p] stands for the combination of the categories *voiceless*, *bilabial*, and *plosive*. The complete IPA can be downloaded from the Internet ([http://www.langsci.ucl.ac.uk/ipa/IPA_chart_\(C\)2005.pdf](http://www.langsci.ucl.ac.uk/ipa/IPA_chart_(C)2005.pdf)), while the most useful and complete source of all facts and phenomena about and around the IPA is the *Handbook of the International Phonetic Association* (International Phonetic Association, 1999). A comprehensive overview is found in Dittmar (2008, pp. 68–80), and there is a very technical and sophisticated presentation in Gibbon, Moore, and Winsky (1997). The SAMPA system, which enables the PC user to apply all IPA symbols (diacritics included) in a particular program, is presented in full technical detail in IPA (1999) and Gibbon et al. (1997).

Although IPA is still used today in nearly all foreign-language learning courses as a basic source for the acquisition of pronunciation, the IPA phonetic profiles of dialect varieties were made by experts for experts. Indeed, these transcriptions never came down to the lay public. The “profiles” disappeared in the archives. Thus, two characteristics mark IPA transcriptions in the middle of the 20th century: They (a) excluded the lay public, as they were unreadable for “normal” members of a speech community; and (b) were restricted to purely phonetic information, leaving out any pragmatic, semantic, or conversational aspects. On the other hand, the large historical tradition of literary transcription in fiction partly compensated for this. Authors like Raymond Queneau (in French), Alfred Döblin (in German), Luigi Pirandello (in Italian), and James Joyce (in English), among many others, created easily readable alphabetic ways of representing oral utterances in their work. These “natural” transcriptions were taken into account by linguists in the last 30 years of the 20th century. Inspired by the large international pragmatist movement (“the pragmatic turn”), linguists developed literal transcription by using easily readable symbols and enriching them by adding nonverbal aspects of annotation (see Jefferson in Atkinson & Heritage, 1984; Schegloff, 2007).

The rise of pragmatics and sociolinguistics in the last 30 years of the 20th century stimulated the broad recording of everyday speech and conversation, and motivated researchers to develop annotations for transcription focusing on pragmatic aspects (pauses, turns, turn taking, and prosody). Good readability was conceived as a presupposition of intensive international exchange and comparability of data based on reliable transcriptions. The progress in conversational pragmatics since the beginning of the 1970s is documented in Schegloff (2007) and for sociolinguistics by Dittmar (2008). This pragmatic turn coincided with the increasing interest of many linguists in founding their theory and methodology on solid empirical data (corpora).

Communicative Social Practices and Transcription Design Principles

Many prominent linguists are interested in a usage-based *construction grammar* founded on corpus data. Applied linguistics (psycholinguistics, sociolinguistics, foreign-language learning, and discourse analysis) is also existentially interested in authentic data from natural communicative genres as a basis for adequate target language training. “Good” grammar is today based on (transcribed) data; these “realistic” grammars are useful for

foreign-language teaching. The transcriber, according to pragmaticians, is no longer only a *Homo faber* doing his or her work but somebody who makes “theoretical” decisions about linguistic explications by choosing a particular coding system. This view has been underlined by Du Bois: “Transcription is theory . . . How we transcribe doesn’t just reflect our theories of language, it also shares them, drawing our eyes to some phenomena while leaving others in shadow” (1991, p. 71). Instead of maintaining the IPA position (exact phonetic transcription by experts), he asks for *discourse transcription* (DT), defining it “as the process of creating a representation in writing of a speech event so as to make it accessible to discourse research . . . The process of DT is never mechanical, but crucially relies on interpretation within a theoretical frame of reference to arrive at functionally significant categories, rather than raw acoustic facts” (p. 73). Du Bois conceives speech as interactive communicative practices in a situational and social context. On the one hand, the transcription design principles (TDPs) should define the minimalistic (universal) standards of transcription; on the other hand, they should deliver a solid account of those characteristics the study is looking at. The following TDPs should be recognized, according to Du Bois (1991, p. 76):

the words spoken, written so as to allow each lexical item to be recognized; an identification of the speaker of each turn; the temporal sequencing of utterances, whether these follow each other in succession or are simultaneous (as when speakers overlap); basic units in which the utterances were articulated, such as turns and intonation units; intonation contour, whether functionally or phonetically classified; accent; fluctuations in timing such as tempo, pause and lengthening; nonverbal noises made by speech event participants, such as laughter, throat-clearing, inhalation; non-utterance events that become relevant to the interaction . . . ; meta-transcriptional and “evidential” comments on the transcription itself.

It is useful to specify the TDPs explicitly for a “gain in theory.” Researchers thus get clear theoretical criteria for an adequate choice of the descriptive and explanatory aims of an empirical study. Du Bois distinguishes five broad maxims, which he comments on in detail (1991, p. 78):

- “1. *Category definition*: define good categories.” The categories should be explicitly defined and sufficiently general (i.e., they should not depend on specific discourse and language contexts).
- “2. *Accessibility*: make the system accessible.” The choice of particular transcription symbols should be realized according to principles of simplicity and optimal readability (i.e., iconic symbols).
- “3. *Robustness*: make representations robust.” The symbols should not be susceptible to confusion, technical deficits, missing distinctions, and so forth.
- “4. *Economy*: make representations economical.” There should be no redundancy, but instead distinctiveness, restriction to the most essential phenomena of spoken language, and easy recognition.
- “5. *Adaptability*: make the system adaptable.” First, there should be a simple set of categories which help to realize a rough transcription; then, further categories which have to be defined in narrow correspondence to these basic categories should enable a fine and detailed transcription.

Edwards (2001, p. 322) gives full theoretical backing to these categories in ordering them into

Table 1 Relation of type of data and the time component

<i>Data type/time</i>	<i>What to consider before you start? (Time 0)</i>	<i>What to add to document? (Time 1–Time n)</i>
Recording-related metadata	Tape labeling conventions, media file formats and naming conventions	Recording medium, date, recorded persons, tape label
Time-free metadata	Staff questionnaire with conventions for assuring anonymity, participant’s name, date and place of birth, sex, professional background, first contact with the L2	See Figure 2
Time-sensitive metadata	Conventions for protocols and other metadata	Intensity of contact with the new language community, language knowledge (subjective)
Annotations/transcripts	File formats and naming conventions, annotation conventions and tools	Files and folders organization, controlled vocabularies for annotation values
Lexical data	Compatibility of annotation formats and exploration tools	Word lists, annotation value lists

1. *general principles*—encoding processes like transcription, coding, and markup; principles of category design such as discriminability, exhaustiveness, and contrastiveness; and principles of visual display such as proximity of related events, visual separability of unlike events, time–space iconicity, mnemonic marking, efficiency, and compactness;
2. *contrasting methods and assumptions*—distinguishing between format- and content-based decisions, the latter discussing words, units of analysis, pauses, prosody, rhythm, turn taking, and nonverbal aspects; and
3. *practicalities*—including technological advances.

While all these principles are debated today, most of them are widely respected. Most important technical progress has been realized in the last two decades. The architecture of different kinds of data has been developed in detail (see Table 1 and Skiba, Dittmar, & Bressem, 2008).

A Cross-Category Grid for the Comparison of Contemporary Programs

Dittmar (2008, pp. 81–165) provides a grid of relevant DT categories and subcategories in the perspective to isolate differences between the available systems (see Figure 1 for an outline).

Figure 1 enables us to compare the symbols selected in a TS for the most important parameters. The central categories relevant for the comparison are in the middle of the figure. The subcategories of each of these are given in a box with the same initial letter as the main category. So with respect to the “design” (D) of a given system, three characteristics (D-1, D-2, D-3) are given; the “turn,” on the other hand, is subcategorized into four

Figure 1 Grid for the comparison of contemporary DT programs

symbolic fields which have to be marked (and when they are not marked something important is missing); and so forth.

Some differences between the three most widely used DT systems are discussed below, with other minor alternative issues.

Conversation Analytic Transcription

The Basic Model

The earliest, most comprehensive, and internationally known DT is that practiced by Gail Jefferson and supervised by Harvey Sacks and Emanuel Schegloff within the framework of conversation analysis (CA) (Atkinson & Heritage, 1984, p. 12; see Schegloff, 2007, for supplements on important problems). It made DT accessible to a broad public of conversationalists all over the world.

Jefferson called the conventionalized principles of literary transcription a kind of *eye-dialect* ("put what you hear in the most iconic way into letters," e.g., *cuz* for 'because', *askedche* for 'asked you'), but with no particular prescription for its coding (see for a good illustration of these principles Jefferson in Atkinson & Heritage, 1984, p. 197). *Readability* and *attention to interactive processes* revolutionized transcription. Most attention is paid to

the fundamental category of *turn*. The borders of and transitions between turns (latching, simultaneity, overlapping, etc.) are conceived as the skeleton of conversational transcription. *Prosody* (differences in pitch, accent, emphasis, speed and volume of speech delivery, etc.) is taken into consideration, although the categories for its representation remain still too superficial (see below on GAT). Aspects of nonverbal behavior are commented on in double parentheses; for example, “((end of the sentence)).”

Schegloff updated Jefferson's conventions (Atkinson & Heritage, 1984, p. 12) in Appendix 1 of his 2007 book. You can listen to model transcriptions for conversations in Schegloff (*n.d.*); other model transcriptions can be looked up in Schegloff (2007, pp. 270–86). CA transcription is widely used by Anglophone conversationalists.

As reasonable as this first revolutionary “simplest systematics” of transcription seemed to many linguists working in pragmatics in the 1980s, critical reviews revealed its weaknesses and missing aspects. Criticisms included the absence of leading theoretical principles (Du Bois, 1991; Edwards, 1993b, 1993c), the underrepresentation of prosodic distinctiveness (Selting, 1996), the arbitrariness of Jefferson's “eye-dialect,” and the nonapplicability of transcription data processing computer programs. For analyzing particular discourse variants (particles, connectives, syntactic options, etc.), the annotations should have been chosen to fit existing PC programs which could handle the basic data for frequency analysis (corpus linguistics). Many conversationalists therefore used CLAN (Child Language Analysis) from MacWhinney's (1991) CHILDES project. Other criticisms of technical aspects, such as import of tools like PRAAT or ELAN, have been raised by Kowal and O'Connell (1995), Sager (2001), and Wittenburg, Skiba, and Trilsbeek (2004). The best modern account of what is needed (tools, computer programs, etc.) is to be found in Deppermann and Schütte (2008). “Radical” conversationalists maintain that a manageable “simple systematics” of transcription is sufficient because researchers should base their descriptions as far as possible on authentic spoken sources.

The GAT Model

GAT (Gesprächs-Analytische Transkription, ‘transcription for the analysis of conversation’) was developed by a group of German (conversational) linguists in order to create a substantial, robust, easily readable, and manageable system which all linguists interested in discourse analysis could use. According to these authors, a standardized version used by everybody in the same way would facilitate cross-conversation analysis and the comparison of data. It was conceived for the transcription of everyday talk and communicative genres; it is very much inspired by Jefferson's CA conventions, but supplies the field of prosody with necessary systematic detail, distinguishing between different qualities of word and sentence accent, pitch register (changes in the pitch contour), and pitch volume (*forte* vs. *piano*, *accelerando* vs. *rallentando*, *crescendo* vs. *diminuendo*). Attention is paid also to types of *pauses*, ways of aspiration, and laughter, among others. GAT distinguishes *basic* and *narrow* transcription, the latter mostly concerned with fine annotations of prosodic aspects. Like the basic model described above, GAT starts with a transcription header specifying the participants involved in the recording, the kind of social encounter, the technical equipment, and relevant observations on the part of the researcher (Dittmar, 2008, pp. 141–5; see Selting, *n.d.*).

GAT is used in Germany (as the most standardized DT) and many other parts of Europe, particularly Austria, Switzerland, France, and Italy. Integrating most of the CA conventions and elaborating annotations for turn (taking) and prosody, it is a valuable candidate for a worldwide standard format of transcription. GAT is not linked to a particular tool of discourse annotation like EXMARaLDA (see below) or CLAN, but stands on its own. GAT 2, a revised version of GAT 1, appeared too late for consideration in this entry (Selting et al., 2009).

First and Second Language Acquisition

CHAT (Codes for Human Analysis of Transcripts), developed by Brian MacWhinney on the framework of the CHILDES project since the late 1980s, offers a rich semiotic repertoire for the representation of verbal, paraverbal, and nonverbal discourse data. The conventions for coding data are tailor-made for studies of first and second language (L1 and L2) learning. On the one hand, there are iconic symbols as in CA and GAT; on the other hand, signs and symbols are used which do not go back to literary transcription and do not have a natural (iconic) analogy to the external world (e.g., “@” for laughter). This aspect of the design is most visible in the conventions for discourse aspects (see for a detailed evaluation Edwards 1992, 1993a). but technically there is no real problem. The great majority of L1 and L2 projects all over the world work with CHAT. L1 and L2 learning is documented nearly completely by the CHILDES system, which consists of three parts:

1. documentation of discourse and talk coded in CHAT;
2. a data bank of transcripts formatted in CHAT (documentation of longitudinal studies, both L1 and L2); and
3. the computer program CLAN, a tool for data analysis.

A detailed handbook on CHAT and CLAN, giving information about all the coding principles and possibilities of data analysis, can be downloaded from <http://childes.psy.cmu.edu>. A great advantage of CHAT is the possibility of defining special tiers in the transcription for coding in detail particular phonetic, phonological, morphological, syntactic, semantic, or pragmatic aspects of linguistic phenomena under study (see in particular Dittmar, 2008, pp. 158–60).

Other Issues

To match the aims of a particular empirical linguistic study, there are still other TSs available. The best and most detailed collection of different approaches is documented in Edwards and Lampert (1993). Skiba et al. (2008) give an overview of decisions, options, and solutions for transcribing, archiving, and analyzing data corpora with different tools according to specific theoretical aims and methodological criteria; for encyclopedic overviews see Edwards (2001) and Gibbon et al. (1997). A fresh account of the most recent developments in the field is Deppermann and Schütte (2008); the pragmatic journals *Pragmatics* and *Gesprächsforschung* (www.gespraechsforschung.de) currently publish articles on transcription.

Problems of an Annotation System for Nonverbal Behavior

There is a quite lively debate about the degree to which nonverbal behavior should be integrated into an overall transcription combining verbal and nonverbal aspects. DT systems like CA and GAT code transcriptions without explicit nonverbal annotations. As mentioned above, they solve the problem by commenting verbally on the context in double parentheses; for example, “((X eats)).” A full account of the state of the art is given by Dittmar (2008, pp. 169–86). One main problem in coding nonverbal behavior is the segmentation of the kinesic behavior. An integrated coding system has been worked out by Sager (2001; 2005), published in German. Sager’s annotation system is quite readable and not too complex. It is, however, difficult to get an adequate picture of an ongoing conversation when lots of verbal and nonverbal symbols appear simultaneously. An integrated transcription is as difficult to read as all the notes of a symphony.

An alternative solution is the interlinear integration of video clips which match, in a well-selected sequence, the turns of talk. The visual correlation of the verbal data promises

a more direct, accessible, and intuitive interpretation of the simultaneous gestalt of verbal and nonverbal. There is good technology available for the integration of pictures into the current transcription (<http://www.lat-mpi.eu/tools/elan>, http://www.mpi.nl/IMDI/documents/Proposals/IMDI_MetaData_3.0.4.pdf).

Computer Programs

Design

The transcription design is a central, but not the only relevant, concern of a sophisticated corpus linguistics. Metadata documentation is an important part of establishing a corpus. Deppermann and Schütte (2008, p. 184) give advice on indicating all details of an audio recording. Another problem is that transcriptions have to be edited. There are three modes in which this can be done.

1. In the *vertical or sequential* mode, each turn is represented in a new transcript line. This mode of writing inherently marks the boundaries of turns. GAT demands a segmentation of lines according to functional and prosodic units. This sequential mode can be handled by the transcript editor EXMARaLDA (see below), which can convert data from one mode into another.
2. In the *partiture* mode, similar to a musical score, every participant in a communicative event is assigned his or her own individual line, which, in principle, gives a potentially endless horizontal axis. Specific transcript editors (e.g., EXMARaLDA; see below) enable researchers to represent talk in such a way that it is conceived of as being located on a continuous (time) line.
3. In the *column* mode, the course of turns is represented vertically from top to bottom, not horizontally as in the partiture mode. Each participant is assigned his or her own column. This mode has advantages for the presentation of asymmetries in talk and for focusing on single speakers. It has been used for the analysis of parent-child interaction and for language acquisition research (e.g., the CLAN editor in the CHILDES project). Therefore, import and export as well as convertibility of annotation files are key features that need to be considered prior to data annotation.

Annotation

Modern annotation tools for transcription, coding, and so on can greatly facilitate direct access to the underlying media and thus profoundly influence the annotation process and its end products. Starting with real (primary) data, the annotation process facilitates the coding of pronunciation and intonation; in that sense, modern transcription can also be seen as a kind of annotation—an annotation of the data stream (Bird & Liberman, 2001). Computer programs that allow direct integration of media and system-independent coding are recommended. Another way to ensure quality is through Unicode-based character encoding and XML-based structures. Table 1 above and Figure 2 illustrate the kinds of data annotated according to specific functions of corpus description. There is a logic to the architecture in the way of ordering (non)verbal data, types of metadata, files and folders organization, and technical and medial representations. A detailed overview of the solution to these problems is found—as an overview of the relevant computer programs and their theoretical basis—in Dittmar (2008) and Skiba et al. (2008). Figures 2, 3 and 4 show how to represent the metadata of informants in a representative pattern.

Intraduction of the informants (first interview)*1. Biographical data/social data*

- 1.1 Blinded name, number, and code
- 1.2 Sex
- 1.3 Date and place of birth
- 1.4 Last residence in Poland
- 1.5 Personal situation in Poland
- 1.6 Education
- 1.7 Training/work in Poland
- 1.8 Arrival in Berlin
- 1.9 Beginning of recordings
- 1.10 Language competence in German
- 1.11 Other languages

2. Initial situation in Berlin

- 2.1 Acquisition of German school contexts (type, length, intensity of the course)
- 2.2 Assessment of language competence in German
- 2.3 Work (type, how many hours per week)
- 2.4 Personal situation/social contacts
- 2.5 Living arrangements

Programs

There are at least three major PC programs which offer enormous resources for handling and analyzing DT data with different, very efficient tools.

1. EXMARaLDA (Extensible Markup Language for Discourse Annotation) is an XML-based system for doing transcription and corpus description by computer technology. The transcript editor allows the conversion of one coding system into another. EXMARaLDA uses a partiture editor (see above) and software tools such as the *corpus manager* and particular *exploration tools* which open large possibilities of storing, processing, exploring, and manipulating data. EXMARaLDA can also import and export other programs, including the following two.
2. PRAAT is a sophisticated program for analyzing all kinds of prosodic phenomena <http://www.slp.utoronto.ca/Assets/SpeechLanguage+Pathology/assets/PrattMan.pdf>, <http://www.fon.hum.uva.nl/praat> or www.praat.org.
3. ELAN is a very efficient anthropological tool of cross-level and metadata description (see Skiba et al., 2008; Wittenburg et al., 2004).

Exploration

Combining metadata and annotation searches expands the possibilities for data exploration. For example, some programs (e.g., CLAN) correlate length of stay with morphosyntactic variables, but only when this kind of information is stored in the conventions chosen for file names. More generally, adhering to data format standards at each stage of the study is of crucial importance, as is widely acknowledged in discussions found in the most important coding manuals, including those produced in conjunction with CHILDES (MacWhinney, 1991), ESF (Perdue, 1993), and LIDES (Barnet et al., 2000). An alternative to existing norms is XML-based formats. These allow easier conversion of data and are future-oriented (see Wittenburg et al., 2004).

Practicalities

Transcription is a time-consuming activity, and high levels of performance and precision are necessary: Talented transcribers are often talented musicians. Transcription is a scientific art. The more reliable it is, the better the observations of everyday verbal behavior. In addition to Dittmar (2008), not listed here because it is in German, the best introductions and tutorials for doing transcription are:

1. Du Bois, Cumming, Schuetze-Coburn, and Paolino (1992)—a DT manual of 225 pages treating all possible problems and giving practical examples and advice;
2. Depperman and Schütte (2008)—practical and, in particular, technical support; and
3. Edwards (2001)—practical and technical support.

Technology and Translation

LYNNE BOWKER AND DES FISHER

The application of technology to translation got off to an early but inauspicious start in the post-World War II period, when initial attempts were made to develop fully automatic high-quality machine translation systems intended to replace translators. Researchers learned, however, that translation was a highly complex task consisting of more than simply word-for-word substitution. Contextual, pragmatic, and real-world information proved very difficult to program, and attention has since shifted to finding ways in which computer tools can assist, rather than replace, professional translators. Indeed, in our current fast-paced, globalized, and information-thirsty society, the use of technology by translators is no longer a luxury but a necessity if they are to meet escalating market demands for the speedy delivery of high-quality texts in many languages.

Computer-Assisted Translation Tools

Many different types of electronic resources and tools are of interest to translators when they carry out computer-assisted translation (CAT). These include electronic dictionaries and term banks, word processors, voice recognition software, corpus analysis tools, terminology extractors and terminology management systems, localization tools, translation memory systems, and even machine translation systems. In addition, it is becoming increasingly common to find a range of such tools integrated into a tool suite or translation environment tool (TEnT), which allows the various elements to interact or the output of one to become input to another. In fact, TEnTs are the most popular and widely marketed translation tools in use today. While individual components differ from product to product, the main module around which a TEnT is constructed is a translation memory (TM), which, in turn, usually functions in close association with a terminology management system (TMS). Detailed descriptions of the operation of TEnTs and their components can be found elsewhere (e.g., Bowker, 2002; Quah, 2006; L'Homme, 2008), but a brief explanation follows since a basic knowledge of how these tools work is key to understanding how they have impacted the translation product, process, and profession.

A TM tool allows users to store previously translated texts and then easily consult them for potential reuse. To this end, source and target texts are stored in a TM database as bitexts. An aligned bitext is created by first dividing the texts into segments—which typically correspond to sentences—and then linking each segment from the source text to its corresponding segment in the translation. When a translator receives a new text to translate, the TM system first divides this new text into segments and then compares each of these against the contents of the TM database. Using pattern matching, the TM system determines whether any portion of the new text has been previously translated as part of a text stored in the TM database. When the TM system finds matches for a given segment, they are presented to the translator. These matches can take a number of forms, including exact matches (identical), fuzzy matches (overall similarity), partial matches (a specific portion is the same), and term matches (a term appearing in the text segment has a corresponding entry in the integrated terminology database). A translator is never obliged to accept the matches identified by the TM system; these are offered only for consideration

and can be accepted, modified, or rejected as the translator desires. Moreover, if no match is found for a given segment, the translator will have to translate it from scratch or send it to an integrated machine translation system to produce an initial draft.

While TM systems are at the core of TEnTs, they are often integrated with TMSs, which can greatly enhance TM functionality. A TMS is used to store terminological information in and retrieve it from a terminology database or termbase. Translators can customize term records with various fields (e.g., term, equivalent, definition, context, source), and they can fill these in and consult them at will in a stand-alone fashion. Retrieval of terms is possible through various types of searches (e.g., exact, fuzzy, wild card). However, termbases can also be integrated with TM systems and work in a more automated way. For example, with an automatic terminology look-up feature, a TMS can scan a new text, compare its contents against a specified termbase, and automatically display records for any matches that are found. If they so choose, translators can then paste the equivalent found on the term record directly into the target text with a single click. Moreover, translators can further automate this step by using a feature known as pretranslation, whereby the system will operate in batch mode to automatically replace any terms in the text with their equivalents from the termbase.

Benefits and Costs

The oft-cited benefits of using TEnTs include increased productivity and improved quality. By recycling relevant portions of previously translated texts, translators can work more quickly. In addition, automatic consultation of termbases results in greater consistency. Quality can also be enhanced by using TM databases and termbases whose contents are specific to certain clients or text types. Several recent surveys of the translation industry (e.g., Lagoudaki, 2006) confirm that an increasing number of translators—across the public, private, and freelance sectors—are indeed availing themselves of such technology, and many claim to have a higher income as a result (Gauthier, 2008, p. 10). Nevertheless, the impacts of technological integration are wide ranging, and potential users must evaluate both the benefits and the costs of translation tools before adopting them.

For example, the type of text to be translated might influence such a decision. Given the way TMs operate, any gain in efficiency depends on the TM's ability to return relevant matches. Texts that are internally repetitive or that are similar to others that have already been translated (e.g., revisions, updates, and texts from specialized fields) will tend to generate useful matches. Texts that are less "predictable," such as marketing material or literary works, will not. Once matches are found, simply being able to automatically copy and paste desired items from the TM database or termbase directly into the target text can save translators typing time while reducing the potential for typographic errors. However, significant gains in productivity are usually realized in the medium to long term, rather than in the short term, because TEnTs are sophisticated tools whose introduction entails a learning curve during which productivity could decline. In fact, a number of translators find these tools so challenging to use that they simply give up on them before realizing any such gains (Lagoudaki, 2006, p. 17).

With regard to quality, CAT tools still depend on human translators; should a client have a TM that it wants used for its work, the translator has no control over its contents. Furthermore, the segment-by-segment processing approach underlying most TM tools means that the notion of "text" is sometimes lost (Bowker, 2006). For example, translators may be tempted to stay close to the structure of the source text, neglecting to logically split or join sentences in the translation. To maximize the potential for repetition, they may avoid using synonyms or pronouns. Moreover, where multiple translators have contributed to a collective TM database, the individual segments may bear the differing styles of their

authors, and when brought together in a single text the result may be a stylistic hodgepodge. Although such strategies may increase the number of matches generated by a TM, they are likely to detract from the overall readability of the resulting target text and thus negatively impact quality.

Professional Implications

Translation technology also affects the professional status of translators, their remuneration, and their intellectual property rights. For instance, some clients ascribe less value to the work of the translator who uses a TEnT. If working with such tools is faster and easier than human translation, clients may ask to pay less for it. When a TM offers matches, should the translator offer a discount? Clients may be even more demanding if they use their own TM to pretranslate a text before sending it to a translator. Yet, even exact matches must be evaluated to determine their suitability for the new target text, and the translator may need to make adjustments depending on the communicative context. In addition, using technology comes with some overheads, such as the time required to update and maintain databases. As a result, new payment models, such as hourly charges, fixed-price contracts, or even a volume-based tiered-pricing model (Joscelyne & van der Meer, 2007b), are beginning to replace traditional fee structures, such as billing by the word or page. Furthermore, the trend away from desktop TM systems toward Web- and server-based access to TM databases is giving more control to clients and less to translators, particularly freelancers. Under this model, translators are restricted to using the client's databases and do not have the option of adding matches to or retrieving them from their own TMs, which makes it difficult for translators to build up their own linguistic assets (Garcia, 2008, p. 62).

Ethical, financial, and legal questions surround the ownership and sharing of electronic translation data. The contents of a TM are source texts and translations, the ownership of which presumably remains with the client. However, when collected as a database, control and ownership become uncertain. Various stakeholders may wish to exchange or sell a corpus, TM database, or termbase, and initiatives such as the TM Marketplace, the TAUS Data Association, Lingotek's collaborative translation portal and Lionbridge's Logoport have been established to facilitate such efforts (Joscelyne & van der Meer, 2007a).

Future Developments

Looking to the future, interest in translation technology will continue to grow, and tools and applications will advance likewise. For instance, the profession is likely to sustain an increased integration of technology such as voice recognition tools, as well as controlled-language checkers and translation quality assurance software. The integration of machine translation with TMs is also on the rise (Joscelyne & van der Meer, 2007b). Researchers are actively working on enhancements to TMs that would see the integration of linguistic analysis (e.g., to neutralize the effects of inflection on matching) or the possibility of identifying the precise sections of the target-language segment that should be preserved or modified in the case of fuzzy matches. Tools to extract bilingual terminology and phraseology from comparable (i.e., non-translated) rather than parallel corpora are also under active development.

Standards such as Translation Memory eXchange (TMX), TermBase eXchange (TBX), and XML Localization Interchange File Format (XLIFF) are becoming more widely adopted (Savourel, 2007, p. 37). The range of available open-source translation tools continues to grow and will undoubtedly increase the uptake of translation technology. Moreover, other technological frameworks are also beginning to emerge, such as the use of wikis for collaborative translation (Désilets, 2007)—often in the context of volunteer efforts—and

4 TECHNOLOGY AND TRANSLATION

crowdsourcing or hive translation, where the work of nonprofessional translators is harnessed (Garcia, 2009).

The profession is also likely to undergo an increased commoditization and sharing of resources such as corpora, TM databases, and termbases, as well as further migration toward Web- and server-based access to these resources (Joscelyne & van der Meer, 2007a, 2007b). In addition, new types of jobs are appearing in the field, such as translation technicians or paratranslators (similar to paramedics or paralegals), who are responsible for managing the implementation and maintenance of translation technology.

Translation technology has clearly influenced translation practices and transformed how we think about the product, goals, and uses of translation work. Technology and translation will continue to evolve and to influence one another, and members of the profession must take care to develop best practices that take into account both the possibilities and the limitations of technology use in this field.

Translation and Interpreting and Bilingualism

CLAUDIA V. ANGELELLI

Introduction

Translation and interpreting are deeply interconnected with bilingualism. Without high degrees of bilingualism, neither translation nor interpreting is feasible. This does not mean, however, that either translation or interpreting is a by-product of bilingualism. Rather it means that high attainment in bilingualism is a precondition for highly proficient translation/interpreting. The relationship between language ability, types of bilingualism, and translation/interpreting performance has not been sufficiently researched.

Studies on the intersection between bilingualism and translation or interpreting do not abound. They have emerged from various fields and have focused on different issues. Examples coming from education—especially in the area of the gifted and talented—and bilingualism are studies that have looked at the ability of certain talented bilinguals to translate or interpret for their immediate communities even at early ages (Valdés, Chávez, & Angelelli, 2000; Valdés, Chávez, & Angelelli, 2003; De Ment, Buriel, & Villanueva, 2005; Orellana, 2009). Studies from educational psychology and psycholinguistics have shed light on how bilinguals process information simultaneously in two languages (Bialystok, 1991; Bialystok & Hakuta, 1994). Research in translation and interpreting studies (Harris, 1978, 1980; Angelelli, 2010) have looked at the ability of bilinguals to act as translators-interpreters and have compared bilinguals and professionals in their ability to assess good performance (Colina, 2008, 2009). These fields of study have conceptualized the interaction between bilingualism and translation/interpreting differently. In the field of translation and interpreting studies, which is the focus of this entry, bilingualism has not been problematized enough. In some instances it appears to be conceived as a monolithic concept (e.g., “true” bilinguals are those with high degrees of proficiency in the two languages; others with lower degrees of proficiency are considered language learners) or it is taken for granted. A prevailing view is that for a professional to be considered bilingual he/she has to exhibit equal mastery of the two languages to be able to work with them or to be able to interpret in both directions (e.g., English into Chinese and Chinese into English). In other words, an interpreter or a translator seems to be considered bilingual only when he/she has attained native-like control of two languages (Valdés et al., 2003).

This conceptualization differs from the prevailing one in the field of bilingualism, which may consider bilinguals all those individuals who have a range of competencies that may not necessarily be the same in both languages. As such a bilingual could be an individual who has minimal competence in reading, writing, speaking, or listening in a second language or may be a person who can make use of two or more languages in everyday situations even with linguistic disfluencies (Valdés & Figueroa, 1994). The truth is that bilingualism is not a monolithic construct; instead it is fluid and varies across the individual's lifetime. Researchers have created typologies to help describe bilinguals' abilities (e.g., Valdés & Figueroa, 1994, pp. 7–20).

Types of Bilinguals

Bilinguals can be classified in several ways. One possibility is to consider the reasons that led individuals to become bilinguals, in other words, if it was an election or a life circumstance that resulted in the person's bilingualism to evolve. Based on the different reasons or conditions in which bilingualism occurs, it may be classified as circumstantial or elective bilingualism (Valdés & Figueroa, 1994, p. 12). Elective bilinguals are those who acquire a language by choice. Either through formal classroom contexts or through less formal learning environments such as home-stay exchange programs, these individuals acquire a language different from their mother tongue. The term "elective" refers to the fact that these individuals do not really need the other language to function in their immediate communities. High-level elective bilingualism is encountered (as well as required) in translation or interpreting classrooms and among practicing translators and interpreters.

In contrast, circumstantial bilinguals need to acquire a second language, the societal language in which they find themselves newly immersed, in order to survive in their immediate communities and participate fully in the new society. These individuals find themselves in a place where their first language is no longer enough to meet their communicative needs (Valdés & Figueroa, 1994, p. 12). Bilingualism thus co-occurs with many other circumstances of a person's life. Some of these can be intermarriage, processes of nationalism and federalism, the need for education, or trade, among other social factors (Valdés & Angelelli, 2003). In addition, languages in contact also lead to circumstantial bilingualism (Appel & Muysken, 1987). For example, a Spanish-speaking Guatemalan family immigrates to the USA, seeking economic opportunities or different educational possibilities for their children. Neither of their languages, Spanish or Mixtec, represents the language used in their new country. Therefore they must acquire a certain degree of proficiency in the new societal language (English) to participate economically, educationally, politically, and socially beyond their immediate community. At the same time, they need to maintain their home languages to be able to communicate with members of their family and their community back home. Their bilingualism is not a matter of individual choice as much as the result of a change in their life circumstances.

Bilingual Typologies and Translation/Interpreting Professionals

Translation and interpreting professionals generally discuss their bilingualism in terms of their working languages (i.e., the languages in which they are proficient enough to work into/out of) rather than in terms of their ability to communicate in them. For this professional group, an equilingual seems to be the model. Professional associations that bring together translators and interpreters (e.g., American Translators Association [ATA] or Association Internationale des Interprètes de Conférence [AIIC]) also use this classification in their professional directories. According to these directories, the strongest language is generally called the A language and the second strongest one is the B language; the third is the C language, and so on (see AIIC, 2010). Often the B language coincides with the elective language of a professional, and the individual's native language is labeled as his/her A language. In addition, interpreters consider their C language as a passive language (as opposed to a working or active language). This means that they can comprehend the C language enough to work out of it but they cannot work into it. As mentioned earlier, however, bilingualism is fluid and this classification may vary throughout one's professional career. For example, if/when a translator/interpreter has moved into a country or region where his/her C language is the societal language, in time his/her C language may change and become a B language, turning a passive language into an active one. In addition, in those professional associations in which there are tests available to certify interpreters/

translators, the distinction between the two languages is also made for certification purposes. Tests measure languages separately. Therefore a translator can be certified only from B to A or A to B (see ATA, *n.d.*), or in both directions.

The concern about demonstrating a high degree of bilingualism and the expectation of working languages are not the same across all types of interpreting or all professional associations. For example, while AIIC has explicit ways of categorizing languages, and AIIC interpreters are expected to identify the languages in their language combination as A, B, or C, this is not the case for the National Association of Judicial Interpreters and Translators or for the California Healthcare Interpreting Association, to name just a couple of others. Interpreters declare a language combination (e.g., English–Chinese) without specifying if they can work into or out of one or the other). Interpreters in the legal or medical setting do not work only into or out of one language: They generally have to work in both directions. This may be due to the nature of the encounters in which they work. Since encounters between health-care providers and patients or between defendants and lawyers involve dialogues in which monolingual interlocutors use only one language, interpreters are expected to broker the interaction by using both languages in both directions (i.e., interpreting out of Chinese into English and out of English into Chinese; CHIA, 2002).

Bilingual Typologies and Translation/Interpreting Classrooms

Circumstantial bilinguals together with elective bilinguals make up the student population of a translation or interpreting classroom. Research in bilingualism has established that not all bilinguals are identical, and they cannot be subsumed under a single standard (Valdés & Figueroa, 1994, p. 7). This fact bears consequences in the education of translators and interpreters. Thus, the notion of circumstantial or elective bilingualism is essential to the fields of translation and interpreting pedagogy. This difference among students impacts directly on the development of their professional ideologies among future translators and interpreters. The elective bilingual generally becomes bilingual through formal education, by taking courses, although it may also be the consequence of elective exposure, for example traveling or spending time in the country where the other (elective) language is spoken. Some circumstantial bilinguals become translators/interpreters in order to help their families and immediate communities communicate. They may think they become translators/interpreters to help or advocate according to their family needs. In sum, since not all bilinguals are alike, and since different types of bilinguals populate translation and interpreting classrooms, it is essential to bear these differences in mind when educating future translators/interpreters. Their different backgrounds, life experiences, and linguistic experiences, as well as their perceptions of their roles and of their own bilingualism, may impact their performance in the classroom (Angelelli, 2010).

In addition, circumstantial bilinguals (also called “heritage speakers” when it comes to their language education, as the language is that of their families and they have been exposed to that language at home) present a wide range of language abilities. Some heritage speakers may have consistent literacy skills, while others may be able to read at an advanced/superior level but have difficulties writing. Others still may have high oral skills but be less able to either read or write. Most heritage speakers have issues with register and at times may have underdeveloped language repertoires. Therefore, in translation and interpreting classes, language ability (as a precondition to translation/interpreting) cannot be taken for granted and degrees (and types) of bilingualism need to be explored. In addition to how students perform, both in terms of language and in terms of translation/interpreting skills, we also have to consider how these different types of bilinguals conceptualize their roles as translators and interpreters and their views on professionalism. Types and categories of bilinguals also represent the different upbringings of individuals

who perform or may perform as translators or interpreters. Their upbringings greatly impact how they understand different situations and shape their expectations as they provide (or receive) a service. Among immigrant and deaf families, communicative needs are constant and professional translators/interpreters are sometimes out of reach, due to either cost or availability. Therefore, these circumstantial bilinguals may grow up thinking translation and interpreting is a more personal than communicative skill; it is a service they have/want to perform for their families. This different conceptualization of what service is, what an interpreter does, and where the boundary between the professional and the personal roles lies is essential to the socialization of future interpreters and the construction of a professional ideology. This is especially important in the education of translators and interpreters. These differences should also be considered at the time of assessing students of translation and interpreting (Angelelli, 2010).

Challenges in Research

The difficulty faced in studying bilingualism *per se*, as well as in reference to translation and interpreting, is that it is confounded by the multitude of conditions and situations in which bilingualism and translation/interpreting may occur. Researchers have pounded questions related to how individuals become bilinguals, the relationship between interpreting and neurolinguistics, the role that each of the two languages plays in the life of the bilingual, and how high levels of bilingualism can be attained, described, and measured without reference to monolingual standards. Research has also looked at bilingual individuals in a situated context and raised questions regarding the relationship between majority and minority monolinguals in situations of language contact. Questions have been about who interprets for whom in which situations, what the social characteristics of the different kinds of interpreters are—in terms of language proficiency, life experiences, socioeconomic status, and ethnicity—and the challenges encountered by interpreters brokering communication between speakers of more and less dominant languages (Valdés & Angelelli, 2003, p. 69).

Researchers (Harris, 1978, 1980; Harris & Sherwood, 1978; Toury, 1984, 1995; Hakuta, 1986; Malakoff & Hakuta, 1991; Zentella, 1997; Valdés et al., 2000; Valdés et al., 2003) have studied the abilities of bilingual children and youngsters in order to determine whether the capacity to translate/interpret is innate or acquired. Their research has also demonstrated the special cognitive, linguistic, and sociolinguistic abilities they exhibit as they perform the role of family (volunteer) interpreter. These studies conducted with bilingual children and youngsters are important to understand the developmental stages of translation/interpreting as well as the acquisition of skills, motivation, and learner strategies. However, they are not without controversy. Some organizations expressly discourage or severely condemn the use of minors in interpreting. Even when there are instances in which bilingual youngsters have to interpret for their parents and members of their immediate families because society cannot meet their communicative needs, the presence of these bilingual youngsters is either denied or regarded with some suspicion. Thus, the implementation of these important studies is, at times, problematic.

Research in Bilingual Youngsters, Translation, and Interpreting

Work with young interpreters, while not focused particularly on bilingualism, contributes to our understanding of life experiences of the individuals who begin to interpret early in their lives (Valdés & Angelelli, 2003). With the exception of early work on young interpreters and translators (Harris, 1978, 1980; Toury, 1984, 1995) and historical work on translation

and interpreting (Karttunen, 1994), very little has been written about the lived experiences of interpreters or about the development of such exceptional types of bilingualism within the field of translation and interpreting studies.

Researchers have observed the role that bilingual youngsters, and many times children, have played in attempting to help their parents by serving as their interpreters or translators (Zentella, 1997; Valdés et al., 2003; Orellana, 2009). These parents and family members who do not speak the societal language receive assistance from their children in everything from placing an order at a restaurant, renewing a driving license, or understanding their doctor (Valdés et al., 2003). Bilingual youngsters step up to interpret for their families and members of their immediate communities in view of: (a) the pressing communicative needs of monolingual speakers, (b) the shortage of qualified interpreters, and (c) the youngsters' own bilingual abilities (Valdés & Angelelli, 2003). By studying bilingual communities, researchers have shed light on how and why monolingual adults and bilingual youngsters team up to cope with communicative needs.

During the first study of young circumstantial bilinguals performing as interpreters, conducted in a high school in California (Valdés et al., 2003), two distinct findings became apparent. First, although some students were classified by their teachers as low-level English speakers (the societal language), their English abilities when interpreting for their families were functional, notwithstanding minor errors and disfluencies, so that the meaning of the message was conveyed and understood. Second, their interpreting skills were sufficiently advanced to allow them to convey the tone and stance of the English message to their parents. Furthermore, in terms of their heritage language, while some second- and third-generation children of immigrant families may lose the command of their native language in the process of adapting to the new culture and its language, the students in the study mentioned above acquired English while retaining their heritage language, Spanish. This ability to use the heritage language effectively while interpreting for family and friends is present not only in bilingual children but also in college students. De Ment et al. (2005, pp. 259–61) report on Asian and Latino college students who continue to be called upon to translate for their parents, as immigrant parents continue at times to feel uncomfortable with their English-language abilities and their limitations in communication.

Another interesting feature of bilingual youngsters acting as interpreters is that many of them perform interpreting with ease for their families with absolutely no training or formal education in either translation or interpreting (see for example Zentella, 1997; Valdés et al., 2003; De Ment et al., 2005; Orellana, 2009). While bilingual youngsters successfully carry out complex communicative activities as language brokers in bilingual interactions, their languages are evolving. Therefore, while their performance may have been marked by disfluencies (Valdés et al., 2003), they nevertheless perform a task similar to that of translators and interpreters. What sets circumstantial bilinguals who choose to interpret for their families and immediate communities apart from translators or interpreters is (a) that they mediate interactions between members of communities with which they have strong bonds and cultural ties and (b) that they do not have the privilege of choosing among the interactions, settings, topics, and situations in which they interpret or translate. They face challenging situations which many times involve the welfare of their own family members. This makes situations much more personal and sensitive. Young interpreters become advocates, usually for a parent or close family member, under exigent circumstances (Zentella, 1997; Valdés et al., 2003). Controversial as these issues might be, they need to be explored rather than taken for granted, judged, or ignored. They reveal important information about the interaction between bilingualism, translation, and interpreting. Life circumstances often shape bilingual youngsters for the roles they play as family translators/interpreters, providing them with the necessary repertoire of habits, beliefs, and values, the appropriate models of emotional response, and the modes of perception which build upon vital skills and knowledge.

Translation and Interpreting: Overview

CLAUDIA V. ANGELELLI, BRIAN JAMES BAER, AND NADJA GRBIC

Within the field of applied linguistics the subfields of translation and interpreting, including signed language interpreting, have experienced explosive growth over the past two decades. The reasons for this are many and varied, ranging from the increasing globalization of the economy to the creation of new multinational political entities, such as the European Union, to a growing recognition that access to quality mediation in crosslinguistic communication is a basic human right. Current immigration patterns, which produce immediate linguistic needs, coupled with instant crosslinguistic information sharing and exchanges made possible by the Internet, such as video conferencing, Skype, and other electronic resources, have greatly increased demand for translation and interpreting services and have highlighted the need to produce more high-quality translators and interpreters.

Recent developments in the study of translation and interpreting reflect these changes in demand and mode of delivery. Technological innovations, while increasing demand, have also contributed to efficiencies in the delivery of translation and interpreting services, as well as in the study of translation and interpreting products and processes. All this has, in turn, accelerated the professionalization of translation and interpreting, as witnessed by the growth of professional associations offering certification and professional development programs, and the emergence of translation and interpreting studies as an independent discipline within institutions of higher education, supported by scholarly journals, book series, publishing houses, and funding opportunities.

Advances in computer-assisted translation and interpreting tools, machine translation programs, video conferencing, and voice over the Internet have made a certain degree of computer expertise a prerequisite for any professional translator and interpreter. Given the high demand for well-trained interpreters, institutions at times rely on telephone or video-conferencing interpreting services to facilitate communication with speakers of non-societal languages. This resource may be especially helpful for speakers of less commonly spoken languages. The appearance of new technologies, in turn, has generated a lively discussion in the field of translation and interpreting pedagogy as to how best to teach and assess the necessary computer skills. Specifically in translation, the fact that many certification exams, until only recently, have been taken with paper and pen suggests a gap between technological innovation in the field and pedagogical response to that innovation. Technological advances, which have helped fuel the rapid growth of the language industry, in turn, have led to a diversification of the workforce. Translation and interpreting training must now prepare students to assume positions not only as translators or interpreters but also as project managers, managers of language services, terminologists, software localizers, quality-control supervisors, and revisers of both human- and machine-generated written and oral texts.

Technological advances have also facilitated the study of translation and interpreting-related phenomena both as a product and as a process, often referred to as descriptive translation and interpreting studies. Controlled collections of texts, or corpora, for example, allow researchers to isolate general patterns across texts, challenging long-standing beliefs with empirical data. The same is true of databases of oral interviews between patients and health-care providers who communicate with the help of interpreters; data generated in this way allow researchers to deconstruct myths of interpreter performance (e.g., that they

2 TRANSLATION AND INTERPRETING: OVERVIEW

are more or less visible in the interaction). Corpora are also increasingly used in translator training programs in order to expose students in a hands-on way to the principles of terminology management while empowering them to create their own resources, tailored to their specific needs. In interpreting pedagogy, teachers have begun to use discourse analysis to explore authentic crosslinguistic exchanges.

In terms of process-oriented translation research, eye-tracking software has shown great potential as a supplement to traditional methodologies, such as keystroke logging and think-aloud protocols, for unlocking the secrets of the translator's brain. In process-oriented interpreting research, studies reveal the strategies used by interpreters in brokering communication. Empirical data allow researchers to describe self-monitoring and correction techniques. These findings are valuable in teaching students of interpreting to use pauses strategically and to determine appropriate degrees of intervention on the part of the interpreter.

Although technological innovations have had a great impact on research agendas in translation and interpreting studies, there is another important influence shaping the study of translation and interpreting phenomena today. That is the continuing influence of poststructuralist theory, or postpositivist thinking, on the conceptualization and study of translation and interpreting. Researchers and theoreticians continue to pursue the implications of translation and interpreting conceived not as the transfer of a message from one linguistic system to another, but rather, as a culture-specific and historically determined rewriting or re-enacting of texts. The influence of sociology and cultural studies on research agendas in translation and interpreting studies has been especially pronounced over the last ten years insofar as its methodologies focus on specific sociocultural configurations and the agents who are produced by them and who, in turn, reproduce them. Methods and concepts from sociology and anthropology have also been crucial in helping translation and interpreting scholars refine and complicate notions of globalization and cultural exchange. In the case of interpreting, scholars now recognize that there are specific sociological issues that arise in the various settings in which interpreting takes place (e.g., conference, court, medical), and that these differences should be reflected in the development of pedagogical methods. Sociological approaches are also useful in exploring the issues that arise from the gap between the supply of professional or qualified interpreters and the demand for service. In studying the issue of volunteer interpreters, for example, scholars have demonstrated that access to services on the part of linguistic minorities does not always equate with access to meaningful and high-quality information, which many times can only be provided by professionals.

In addition to entries on translation and interpreting, this section includes a number of entries that deal specifically with signed language interpreting. Signed language interpreters mediate between deaf and hearing people and work between two different language modalities, spoken and signed. They share the same professional standards as spoken language interpreters in terms of role, ethics, and training, but, as the development of the profession largely depends on social and cultural contexts and institutional constraints, the practice of signed language interpreting (SLI) differs internationally in terms of stages of professionalization, provision of interpreters, and interpreter training. Signed language interpreters typically work in educational, legal, medical, mental health, social service, and employment settings, as well as in less common, but nevertheless important settings, such as religious, conference, and performance interpreting.

SLI research is a subdiscipline of translation and interpreting studies; it has witnessed a dramatic increase in research, employing a range of different theoretical approaches and research methods. Although current research focuses on various domains of interpreting, the majority of SLI research reflects the settings in which SLI most commonly occurs—community interpreting and educational interpreting. Research topics, therefore, often

include questions of interpreter role and ethics, which are also well represented in interpreting studies as a whole. Apart from sociological and sociolinguistic approaches, studies have been conducted on the cognitive process involved in SLI and on the (quality of the) product. From a methodological point of view, research includes discourse analytic methods, ethnographic methods, survey research, and experiments. Several papers have been published on sight translation/sight interpreting and signed language translation (SLT) of a range of texts, such as Web sites, psychological tests, educational resources, and children's books. SLT is a relatively new phenomenon, which emerged as a consequence of advances in information and communication technology. It comprises the interlingual and intermodal transfer of fixed or frozen (written) texts in spoken languages into fixed or frozen oral or signed texts (video) in any signed language.

While there are significant differences in terms of the training and practice of translators, interpreters, and signed language interpreters, all three subfields are dedicated to the exploration of cross-cultural communication, broadly understood, and are today experiencing rapid expansion due to a host of issues linked to processes of economic, political, and cultural globalization and to technological advancements. The entries below reflect the major developments in the areas of theory, pedagogy, practice, and technology, and are meant to provide a roadmap for those interested in navigating three interrelated fields that are among the most rapidly developing in the area of applied linguistics.

Translation Theory

MARIA TYMOCZKO

General Considerations About Theory

The current concept of theory in academic disciplines began to develop in tandem with the scientific revolution during the early modern period, with most parameters of the concept of theory having been worked out in the natural sciences. Thus, it is no surprise that the word *theory* is relatively new in English, first attested in the last decade of the 16th century, nor is it a surprise that the word has held a variety of meanings during the last 400 years as the natural sciences themselves have shifted their understandings of the relationships binding theory, hypotheses, experiments, and data. It follows that in order to understand the concept of theory, it is more useful to see theory as a term of art or a technical term rather than a word whose meaning and usage are most apparent in ordinary language. As a result, investigating the use of theory in ordinary language as a means of understanding the concept of theory—a common strategy in the philosophy of language since Wittgenstein—fails in this instance. To delineate theory in applied linguistics, particularly with reference to a relatively new field such as translation studies, it is essential to acknowledge the following: the concept of theory in any academic field must be framed by the history and methods of the natural sciences, specifically the relationship between theory and empirical practices in these fields.

Thus, definition 4 of “theory” in the *Compact Oxford English Dictionary* (1971) (hereafter *OED*) is the relevant entry for understanding theory in translation studies and other areas of applied linguistics: “a scheme or system of ideas or statements held as an explanation or account of a group of facts or phenomena; a hypothesis that has been confirmed or established by observation or experiment, and is propounded or accepted as accounting for the known facts; a statement of what are held to be the general laws, principles, or causes of something known or observed.” Definition 4 is attested earlier than and contrasts with definition 6, the definition that the *OED* calls the “loose or general sense”: “a hypothesis proposed as an explanation; hence, a mere hypothesis, a speculation, conjecture; an idea or set of ideas about something; an individual view or notion.” Often applied linguists and translation studies scholars are not clear about these different meanings of the word *theory*, thus tenaciously seeing theory in arguments that are in fact merely “individual views or notions” and “speculations.” This is particularly a tendency of scholars with little training in the natural sciences who do not understand the reciprocal relationships that bind theory, the development and testing of hypotheses, experimental design and execution, the definition and collection and examination of data, and the consequent reexamination of theory on the basis of those investigations—in short experimental methods in general (see Tymoczko, 2007, pp. 140–86).

Translation studies emerged as an academic field after World War II and many of the field’s initial preoccupations and investigations were motivated by the use of translation during the war, particularly the role of translation in intelligence and propaganda. During World War II there were many people involved in coding and decoding all around the world and operatives were translating to and from more languages than had ever before been used concurrently for strategic purposes. Moreover, because the war had a global

scale and reached into normally isolated areas, an awareness of the range and diversity of the world's languages and cultures came to the fore, even as translation among them was necessitated. This historical context for the development of translation studies explains why earlier generalizations about translation are not necessarily theoretical, both because they do not account for a sufficiently broad range of cultural and linguistic data related to translation and because such statements (e.g., the discourses about translation in both Europe and China before World War II) were formulated without regard to the nature of theory in an academic discipline per se (see, e.g., the compendia in Robinson, 1997a, and Cheung, 2006a).

As it has been constituted, translation studies has included the study of both written translation and interpreting; in what follows, therefore, the term *translation* refers to both the written and oral modes of transposition across languages and semiotic codes (see Jakobson, 1959). Since the 1950s a succession of schools of thought about translation has ensued, with most making some lasting contribution to translation theory defined in the sense of coordinated hypotheses that have been confirmed by observation and that account for the known phenomena. Many of these schools have published extensive numbers of case studies that have generated data with theoretical implications. Some of the most important approaches to translation studies that have left their mark on translation theory include linguistic approaches, functionalist approaches, systems approaches, cultural studies approaches, and more recently internationalist approaches (see Tymoczko, 2007, pp. 15–53). None of these schools can be rigorously separated from the others; together they confirm the principles of translation theory outlined below.

Theoretical Principles Currently Accepted in Translation Studies

The following formulations summarize the durable theoretical principles of translation studies that have emerged since World War II. Note that there is a radical difference between outlining agreed tenets of translation theory and reviewing the history of attempts to theorize translation. This entry has the former as its goal rather than the latter, thus subsuming the contributions of some venerable schools of translation studies (e.g., *skopos theory*; see Nord, 1997) under a broader rubric. Note as well that in the following theoretical formulations, the term *translation* can refer to either process or product. This semantic overlap is a function of English rather than a universal; however that may be, both aspects of translation must be accounted for in translation theory (see Holmes, 1994, pp. 67–80).

1. Translation involves negotiating fundamental linguistic and cultural anisomorphisms and asymmetries. Examples might include lexical asymmetries based on contrast, such as *yes/no* in English vs. *oui/non/si* in French versus a double lexical void in Old Irish which indicates assent and dissent by other means. Lexical asymmetries also are apparent in differences in semantic fields of corresponding words across two languages and in divergent patterns of semiosis. There are also morphological asymmetries such as the tense differences between languages that require distinguishing completed action from continuous or habitual action and those that do not, or distinctions in languages that mark gender or number and those that do not. Morphological asymmetries are often large when two languages come from different language families (such as Indo-European and Semitic languages). Syntax is also often highly variable between languages, particularly in translation across two language families, and idioms are by definition almost always asymmetrical across languages. Similarly, cultural asymmetries are inevitable between any language pair, however close, exemplified by differences in values that affect the understanding of concepts (e.g., individualism);

differences in material culture such as variations in tools and technology; means of differentiating and organizing a society; or differences resulting from climate and the natural world, such as variations in flora, fauna, and the like (see Jakobson, 1959). During the process of translation, such anisomorphisms and asymmetries require that translators make decisions and choices about representations in the target text (TT) created by the translator. Anisomorphisms and asymmetries also require that a translator make choices about the interpretation of meaning; decisions about the meaning of the source text (ST) and choices about the construction of meaning in the TT. (See Vinay & Darbelnet, 1958/1995; Nida, 1964; Catford, 1965; Fawcett, 1997.)

2. As we have seen, translation involves decisions and choices about meanings in the ST and constructions of meaning in the TT, where a text is understood as being either oral or written. Because meaning is language specific and meaning is conditioned by contextual relevance, translations and their source texts have different meanings. It is therefore misleading to say that the task of the translator is to preserve meaning or to create a text that has the same meaning as the source. (Classic discussions of this topic include Jakobson, 1959; Quine, 1959; Catford, 1965; a review of the issues is found in Tymoczko, 2007, pp. 265–309.)
3. Meaning in a ST or a TT extends far beyond semantic meaning. In translation a practitioner must pay particular attention to functional aspects of texts; the functionalist dimension of texts is central in every type of translating, from translation of sacred texts and advertisement localization to community and legal interpreting. Literary translators are called upon to be attentive to functionalist aspects implicit or explicit in form. The patronage and the material or physical basis of the production of an oral or written translation can also affect its meaning. (See Nida, 1964; Catford, 1965; Nord, 1997; Tymoczko, 2007, pp. 265–309.)
4. Because translation involves decisions, choices, and constructions related to meaning, there is no single correct way to translate. Translation equivalence is a posteriori in nature. The particular configuration of equivalence in a translation can be defined only by descriptive studies of the actual translation in relation to context. The a posteriori nature of translational equivalence, entailed by the processes and practices of translation, led Gideon Toury to propose the following a posteriori definition of a translation: “any target language text which is presented or regarded as such within the target system itself, on whatever grounds” (1982, p. 27; See 1980, pp. 14, 37, 43–5). (On the a posteriori definition of the status of a translation, see also the arguments in Hermans, 2007, pp. 1–25.)

It follows from the theoretical principles elaborated thus far that translation equivalence is a form of similarity rather than identity. Like similarity in any domain (as cognitive scientists have demonstrated), the range of possible similarities that can be perceived and constructed in the process of translating is large and the possible ways of constructing similarity in the translation of any text are highly variable (see Broeck, 1978; Arduini & Hodgson, 2004; Tymoczko, 2004, and sources cited). Descriptive studies have shown that cultural norms and ideals about translation, which impact on notions of translation equivalence, have varied widely across time and space.

5. An entailment of the decisions, choices, and constructions involved in translating is that translation is a metonymic process. Translations are partial representations of their source texts. Translators also introduce into their translations additional metonymies that have significance related to the target languages and cultures. Such metonymies and partialities are not defects of translation; they enable translated texts to be received and understood by target audiences, to participate in discourses of the target culture, and to speak to the concerns of the audience. A translator’s choice of metonymies or partialities can have a variety of functions ranging from esthetics and

representations of the target text to its ideology and political import. (See Levý, 1967; Holmes, 1994, pp. 35–52; Tymoczko, 1999, pp. 41–61; Tymoczko & Gentzler, 2002, pp. xvii–xviii.)

A corollary of this principle is that the metonymic nature of translations guarantees the afterlife of source texts. Textual metonymies in translations deliver texts in terms that target audiences can relate to despite having other languages and traditions or living in other contexts, cultures, and time periods. Paradoxically, therefore, source texts are dependent for their continued survival on translations as much as translations are dependent for their existence on source texts. (On the afterlife of texts, see Benjamin, 1923/1969.)

6. Translation equivalence can be stipulated explicitly or implicitly, as can any linguistic behavior including grammar or lexis. In the case of translation, equivalence can be stipulated or prescribed by general cultural norms or by a particular authority in a specific context, such as a business, a patron, a religious institution, or a government. For the development of translation theory and the understanding of translation behavior in general, however, descriptive approaches that move beyond culturally bound norms and prescriptions are essential. A broad sampling of translation processes and products must be investigated with reference to their specific contexts in time and space. (See Toury, 1980, 1982, 1991, 1995; Hermans, 1985.)
7. Translation is a form of rewriting and as such has many commonalities with other forms of rewriting including versions of texts adapted to specific media (such as film), versions adapted to specific audiences (such as children), editions, anthologies of texts, literary and textual histories, critical studies of texts, and so forth. Investigating the commonalities that translations share with rewritings illuminates both the processes and products of translation, and vice versa. The identification of translation as a form of refraction or rewriting is related to the metonymic nature of translation. (Foundational studies taking very different approaches to the question include Lefevere, 1982a, 1985, 1992; Holmes, 1994, pp. 23–34; Vieira, 1994.)
8. Because translation involves choices and because strategies of translation vary so widely, like other forms of cultural production, translations are best seen in the context of cultural systems. On the level of the texts themselves, translations and translation choices relate to cultural systems such as language, the repertory of text types, and poetics. Translations themselves form subsystems of textual systems—notably literary systems—and collectively can be grouped by parameters such as function, audience, text type, formal effects, and patronage. Translations are in turn embedded in larger social and cultural systems, including economic, patronage, political, and ideological systems. To understand the metonymics of a translation and its function in a culture, it is useful to investigate its position using a systems analysis that takes in all these levels. (See Even-Zohar, 1978, 1990; Toury, 1980, 1995; Hermans, 1999.)
9. Translations are an ideological and political form of cultural production. The second phase of descriptive studies has clearly documented the political nature of translation, ranging from postcolonial and feminist aspects of translation to translations that have figured actively in the service of ideological movements and political programs. Ideological effects are often particularly apparent in interpreting. Because translation is highly ideological and has an important role in shaping culture, societies often control or even limit translation through a variety of means ranging from prescriptive norms to censorship. (On these issues see Lefevere, 1982b; Venuti, 1992, 1995, 1998; Simon, 1996; Flotow, 1997; Robinson, 1997b; Bassnett & Trivedi, 1999; Tymoczko, 1999; Simon & St-Pierre, 2000; Davis, 2001; Merkle, 2002; Tymoczko & Gentzler, 2002; Calzada Pérez, 2003; Baker, 2006; Tymoczko, 2010a.)

10. Translation is a cluster concept. Ideas about translation have varied widely across time, place, culture, and language. It is not possible to specify necessary and sufficient conditions that can be used to identify all instances of translation and that at the same time exclude all non-translations across time and space. Toury points to the nature of translation as a cluster concept in defining translation as a culturally bound practice that has an a posteriori nature, quoted above in principle 4. Because translation is an open practice and because new forms of translation can always be invented, translation is an open concept in terms of both its processes and its products (see Tymoczko, 2007, pp. 54–106.) The nature of translation as a cluster concept is perhaps most clearly seen in the widely divergent conceptualizations of translation in the varied languages and cultures of the world and in the widely different documented histories of translation internationally. (Examples are found in Rose, 2000; Hung & Wakabayashi, 2005; Hermans, 2006.)

Conclusions Implied by These Theoretical Principles

Stated directly and simply as above, these basic theoretical principles of translation studies may seem to be a slender achievement for a field that is half a century old. As with the principles of other established theories (such as the theory of gravity or germ theory), they may even seem obvious. Each principle, however, has a broad and deep reach. Taken together these theoretical assertions provide an integrated framework that serves to explain the data associated with observed translation products and processes. In some cases they also have predictive power. Because translation is an open concept issuing in an open set of examples, however, translation theory cannot aspire to being primarily or infallibly predictive.

In the exposition of the principles above, there have been obvious crosscurrents. For example, the choices that translators must make in negotiating linguistic and cultural anisomorphisms and asymmetries are directly related to the metonymic aspect of translation and also to the ideological nature of translation as process and product. The metonymic aspect of a translation is also an entryway into understanding how a translation differs in meaning from the source text and how a translation can profitably be approached from the point of view of systems analysis. In turn it is a short jump to seeing that similarity is the relationship binding source texts and their translations, with translational equivalence being an a posteriori notion. Finally the metonymic nature of translation is also a primary reason that translation is a cluster concept.

These interlocking theoretical tenets also explain the vast divergence that many translations exhibit when compared with their source texts: choices about how to negotiate linguistic and cultural asymmetries, the construction of meanings in translation, the variant ways that different types of meaning can be privileged, and the nature of rewritings in general all contribute to significant types of divergence in a target text. Such divergence is often notable, for example, in advertisements and media productions, and in interpreting. The theoretical principles elaborated here explain the popularity of the new term *localization* that has emerged in response to challenges posed by translating for the new media, differentiating new concepts of translation from old Eurocentric stereotypes of translation being primarily a form of “carrying across” (see Tymoczko, 2010b).

The crosscurrents indicate that the division of translation theory into a definitive number of principles is essentially arbitrary: one might choose to divide some of the foregoing principles (e.g., designating Benjamin’s proposition about the role of translation in the afterlife of texts as a separate principle rather than a corollary) or to join others. Such decisions about segmentation of the theory are essentially trivial; what is much more important is to see that the principles form a dense and consistent conceptual web.

The well-woven nature of these principles speaks to the strength of the theoretical framework that the field of translation studies has begun to develop: it is an integrated framework in which the various principles intermesh and mutually support each other. Together they facilitate investigation of data, in part by allowing the development of hypotheses that serve to interrogate translation processes and products consistently across a broad range of contexts. The framework is also flexible enough to accommodate discoveries associated with new data through reformulation or expansion of some of the principles of the theory. The principles are also amenable to being elaborated in greater delicacy in response to new data. Such expansion can be seen, for example, in the detailed investigations undertaken of the functional aspects of translation processes and products, discussed above in principle 3. Similarly detailed examinations of the role of norms in translation have been undertaken, thus extending the articulation of principles 4–6 (see, e.g., Hermans 1991, 1993, 1996). Moreover, this repertory of theoretical principles is open: it is likely that additional theoretical principles will emerge in translation studies in the near future and that they will be able to be incorporated into the existing framework.

This is all to say that translation theory as it has been developed thus far sets a firm foundation for research on translation within the discipline of translation studies. It is comprehensive and adaptable enough to support the reciprocal relationships that bind theory, the development and testing of hypotheses, the definition and collection of data, the experimental methods of empirical research in general, and the recursive rethinking of theory required by the results of such research. The foundation seems broad enough, deep enough, and flexible enough to be durable as the discipline of translation studies continues to grow. Whatever major shifts in translation theory might be projected, most of the foundational theoretical principles about translation discussed above will endure and be incorporated into future paradigms of translation theory (see Kuhn, 1962).

Together these components of contemporary translation theory also have powerful implications. For example, if taken seriously, they make it impossible (or at least impracticable) to teach translation in a narrow, prescriptive manner or to inculcate rigid, automated behaviors in students, except when such prescriptions serve very local and limited norms. (Here it is necessary to distinguish the teaching of language competence from the teaching of translation *per se*.) Indeed the theoretical framework that has emerged in translation studies indicates that translation pedagogy must be extraordinarily open so as to prepare students for the actual challenges of translating metonymically, responding to context and shifting norms as time and culture themselves change.

Similarly these theoretical principles indicate that ethical questions are central to the task of the translator and the role of translation in cultures. The choices that translators must make in adjudicating linguistic and cultural differences, the construction of meanings in target texts, the metonymic relationships between source and target texts, the nature of rewriting, and the ideological aspects of translation all indicate that there is a powerful ethical aspect to translation. Translators are important shapers of cultures, both source cultures through their representations and target cultures as well. In the limiting case the ethical responsibilities of translators extend globally, far beyond loyalty to their employers. This moral dimension to translation is seldom acknowledged in statements of professional ethics promulgated by professional associations of translators.

Difficulties in Formulating Translation Theory

The formulation of a durable translation theory has been impeded by a number of factors. Most important has been lack of attention to a sufficiently broad base of data from which theoretical conclusions can be drawn. General theoretical principles must accommodate data from the broadest possible range of cultures, must include data about the past as well

as the present, and must apply to any arbitrary pair of languages. Because the data base upon which translation theory is formulated is so large, it is difficult to find scholars or research groups who can muster a sufficiently broad perspective to formulate durable theoretical proposals. Particularly pernicious is the tendency of scholars who promulgate theoretical assertions based on contemporary professional translation practices in a single culture area and who even set aside what they consider to be marginal cases in their own cultures—for example, community interpreting or translation in oral cultures both past and present.

The question of incorporating a sufficiently broad base of data in formulating translation theory is but one aspect of a larger problem in translation studies, namely widespread scholarly lack of expertise in the methods and practices of empirical research. In a great deal of research and writing on translation, inadequate understandings about the relationship of theory and hypothesis, methods of collecting and analyzing data, and appropriate procedures related to sampling and reproducibility of research have constituted barriers to the development of durable translation theory (Tymoczko, 2007, pp. 140–86).

The development of translation theory has also been hampered by Eurocentric dominance in the field of translation studies. Translation has burgeoned in Eurocentric cultures since World War II, both as a consequence of the role that translation played in the war and as a result of the language policies of the European Union. The decision of the European Union to retain as official languages all 23 official languages of the member states of the EU has resulted in the European Commission being the largest employer of translators in the world. The Commission has rather strictly regulated translation policies and practices, however. As a consequence much of what has been written about translation in Europe during the past several decades has implicitly fallen within the framework of contemporary translation pragmatics in Europe and has addressed issues most pertinent to European languages and cultures. What has passed for theory in this context has inevitably tended toward a fairly narrow purview that rarely is applicable to an internationalist view of translation throughout history.

The rise of English as the dominant global language has similarly tended to impede the development of translation theory applicable to a broad linguistic, cultural, and temporal foundation. Because English has increasingly become the dominant language of the discipline of translation studies, the vocabulary of English itself (see Lakoff & Johnson, 1980) issues in theoretical concepts and hypotheses that tend to be posed in terms of Eurocentric perspectives (see, e.g., Susam-Sarajeva, 2002; Cheung, 2006b; Lianeri, 2006). Misleading Eurocentric pretheoretical presuppositions—ranging from the assumption that societies are normally monolingual or that translation is normally a procedure undertaken by a single individual (rather than a team) to the belief that the concept of translation itself can be defined by necessary and sufficient conditions—assumed by many writers using English and other European languages have also undermined attempts to theorize translation studies (Tymoczko, 2006). The problem is exacerbated by the spread of Eurocentric pragmatics and Eurocentric norms of translation within the economic climate of globalization; as a consequence of economic incentives, translation pedagogy internationally is often based on materials developed in Eurocentric contexts and written originally in English (Tymoczko, 2009, p. 405).

Finally, current nationalism and ethnocentrism in general also work against the development of durable translation theory. What has been said above illustrates the problems of Eurocentrism, but similar problems are found in other parts of the world. For example, in China debate ensues about whether Chinese scholars should develop a theory of translation that is independent of Western influences, based solely on Chinese translation traditions. *Prima facie* it should be obvious that it is not possible to develop a comprehensive and successful ethnocentric theory with respect to translation practices and products that are

ipso facto cross-cultural. Whatever the geographic center of an ethnocentric approach to translation, such accounts can scarcely aspire to the status of being theory in the sense we began with: theory “accounting for the known facts” and “being a statement of what are held to be the general laws, principles, or causes” of the observed phenomena of translation across time and space.

Translation Tools

KEIRAN J. DUNNE

In the wake of the digital revolution and the advent of the knowledge economy, the concept of “tool” has expanded beyond its traditional meaning of an implement for performing or facilitating mechanical operations to encompass specialized software applications that help users accomplish specific tasks on computers. In this way, translation-specific applications are typically referred to as “translation tools.” More than mere jargon, this usage underscores the commonalities between specialized software applications and their mechanical forebears: Both are operated by people; both are designed to facilitate specific tasks; and both are only as good as their operators. This entry offers an overview of translation tools, the problems they have been designed to solve, the ways in which they have evolved, and their limitations, with a focus on their primary components: terminology management and translation memory.

Terminology Management Tools

Since the 1960s, it has been clear that terminology is the primary challenge posed by the translation of commercial, technical, and scientific information (Krollmann, Schuck, & Winkler, 1965; Schulz, 1971; Wright, 2001). Over the past several decades, the evolution of science and technology has given rise to new concepts and terms at such a rapid pace that even specialized translators are unable to keep abreast of all of the pertinent literature in the field, let alone document all of the new terms (Schulz, 1971). In addition, most translators are not subject-matter experts (Goetschalckx, 1979; Woyde, 2001). Consequently, when they encounter terminological problems in language for special purposes, as in scientific and technical texts, translators need full information on the use of the terms in the given field, including examples of actual usage in context, in addition to definitions and technical information (Goetschalckx, 1979). Finally, terminological problems tend to be magnified by the “stovepipe” or “silo” effect. The compilation of glossaries and other terminological data on paper or in the brains of individual translators hinders access to that information by other potential users. Disseminating terminological data via paper printouts and dictionaries is laborious and costly. In the absence of effective mechanisms for coordinating terminological research, documenting the findings, and sharing the data, terminology work often involves duplication of effort: “more often than not, each translator does research that has already been done” (Dubuc, 1972, p. 207). These factors explain why searching for the proper term is the single most laborious task and the primary source of errors in technical translation, and why translators may spend as much as 75% of their time researching and consulting terminological resources (Krollmann et al., 1965; Automatic Language Processing Advisory Committee, 1966; Dubuc, 1972; Wright, 2001).

In the 1960s and 1970s, translation departments of government entities and large companies, including the Terminological Bureau of the European Coal and Steel Community, the West German Federal Armed Forces Translation Agency, the French Association for Standardization, and the Siemens company, addressed these problems by developing multilingual terminology data banks (centralized terminology repositories in digital format) to (a) provide information about individual words and phrases (definitions, examples,

2 TRANSLATION TOOLS

translations); (b) create glossaries specifically for the texts being translated; and (c) produce up-to-date specialized dictionaries and glossaries for general use (Hutchins, 1978).

The advent of centralized term banks simplified the creation and maintenance of terminological records; moreover, by enabling networked access to the terminological data and output via either a screen display or paper printouts, such systems provided a relatively rapid, easy, and cost-effective way to share terminological data (Felber, 1983). Users reported that text-related glossaries that had been created using centralized term banks enabled quantitative and qualitative improvements in translation work (Krollmann, 1974). However, early term banks were developed on and for mainframe computers. Therefore, access to these systems was limited to translators working for the governments, universities, and large companies that owned them, as mainframes were prohibitively expensive for personal users.

This situation persisted until the commoditization of the personal computer (PC) in the 1980s and the appearance of mass-market tools that provided access to terminology from within a word processor, giving translators “complete freedom to create translations without burdening them with the mechanical task of constantly looking for terminology” (Good, 1988, p. 91; see also Wright, 1988). However, early desktop terminology management tools presented a number of limitations. For example, they did not allow networked access and offered only unidirectional search and retrieval.

The advent of the Internet fueled the development and rapid growth of the market for outsourced professional translation services in the late 1990s and early 2000s (O’Hagan, 1996; O’Hagan & Ashworth, 2002). However, the disaggregation of translation work proved to be a two-edged sword. Although it allowed translators located anywhere in the world to work with clients located anywhere in the world (provided that each had a data connection), the decentralization of project teams—and thus of linguistic assets such as terminology databases—raised the risk of inconsistency, especially when projects involved multiple translators or when translation team members changed from one project to the next. Thus, since the early 2000s there has been a move back toward centralization with the development of server-based terminology management tools, accessible over the Web.

Although the critical role of terminology in the translation process has been understood for four-plus decades, terminology management tools are not widely used in current professional practice. The causes of this neglect are twofold. On the one hand, proper operation of the tools requires knowledge that many translators do not possess. For example, use of SDL Trados MultiTerm and other concept-oriented terminology management tools requires knowledge of data modeling. One cannot simply launch such programs and begin entering terms; one must first model the structure of the term entry to be used within the application; only then can the user begin entering and documenting terms. On the other hand, many companies and large organizations perceive terminology management as a time-consuming, labor-intensive activity that is outside of their core business, not realizing that terminology is a valuable knowledge asset (Warburton, 2001). This problem is compounded by the difficulty of calculating the cost of managing—or of failing to manage—terminology (Wright, 1998).

Translation Memory Tools

Although terminology managers enable translators to address what is arguably the most critical variable in the translation process, they do not offer what many translators today would consider the key functionality of translation tools: a means of “recalling” previously translated material. According to cognitive scientists, humans can only hold seven chunks of information (plus or minus two) in short-term memory at any one time (Miller, 1956; Mandler, 1967; Simon, 1974). The inherent constraints on short-term and long-term human

Figure 1 On-the-fly translation memory creation: segmentation of source text, translation of individual segments, and storage of translation units © 2011 Keiran J. Dunne

memory have important ramifications for translation. Recognizing that texts requiring translation were often repetitive, or included material from other previously translated documents, or both, Krollmann (1971), Arthern (1979), and others proposed computer-based systems for storage and retrieval of translated material. This concept of translation reuse, although well understood in the 1980s, was not widely implemented in translation tools until the 1990s due to limitations of the then-current technology, and has since become known as “translation memory” (TM).

TM tools help translators recall and reuse previous translations. Some TM tools integrate into a word processor, such as Microsoft Word; others offer word-processing-like functionalities in a dedicated translation environment. TM tools divide the text into chunks, or segments. Segmentation rules are typically based on punctuation and formatting marks. In this way, the user can decide whether the tool should segment the text whenever it encounters a specified punctuation mark (e.g., a period, tabulation, new line character, or paragraph mark). In practice, texts are most often segmented at the sentence level. As the translator works through the text, each source-language chunk is stored along with its corresponding translation as a *translation unit*; the repository in which the translation units are stored is known as a *translation memory* (see Figure 1).

TM tools not only store translated segments but also retrieve them for reuse. The tools compare segments in the file being translated to the contents of the translation memory and retrieve full or partial matches according to the minimum match threshold defined by the user. This analysis and retrieval functionality relies on character-based matching. The tools do not understand the meaning of sentences being translated or that have previously been translated and stored in the translation memory. Instead, they compare the string of characters in a given source-language segment to the various source-language segments stored in the translation memory (see Figure 2).

An example will serve to illustrate the mechanics of translation reuse. Suppose that a translator encounters the sentence, “An error occurred while opening the file.” This sentence contains a total of 41 characters, including spaces. If the translator has previously translated this particular sentence, the tool will retrieve and insert the corresponding target-language equivalent into the working document and indicate that it is an exact match, typically using some form of color-coding. The translator can then confirm the

4 TRANSLATION TOOLS

Figure 2 The mechanics of translation reuse © 2011 Keiran J. Dunne

match and proceed to the next segment. Suppose that the translator has not previously encountered this exact sentence, but has translated a similar one, such as “An error occurred while copying the file.” In this scenario, because the two sentences are similar but not identical, the source-language segment stored in the TM (and by extension, the target-language equivalent) is said to be a *variable match* or *fuzzy match* compared to the new source-language sentence. From the perspective of the TM tool, which assesses equivalence using character-based matching, the two sentences differ only by seven characters (“copying” vs. “opening”), so the translation stored in the TM is deemed to be an 83% match for the current source sentence. If the minimum match threshold is set to 83% or less, the tool will retrieve and insert the corresponding target-language sentence into the working document, and the translator can simply edit the differing portion of the target segment instead of having to translate the entire segment from scratch (see Figure 2 above).

Some tools take the concept of matching further and offer an “exact” or “in-context” matching functionality. Such a match occurs when the segments that immediately precede and follow the active segment are identical in the document being translated and in the translation memory. To enable greater time savings, current TM tools offer both pre-translation and automatic propagation of full and fuzzy matches downstream in the active file, allowing the translator to move from one translatable segment (or variable match) to the next, instead of working through every single segment in the file.

In addition to the storage and automatic comparison/retrieval functions described above, TM systems also offer a query or concordancing functionality whereby the user can search for occurrences of a given term, phrase, or sentence in the TM. The tool will then retrieve and display the source segments in which the search string appears, along with the corresponding translations, up to the maximum number of results specified in the settings. In this way, translation memory not only enables reuse of previous translations, but makes it easier to achieve consistency in translation, since translators are not forced to rely on their memory of how they translated a given expression in the past, but can search for and retrieve the specific source term or phrase and then find and reuse the corresponding translation.

Finally, current-generation TM tools offer “as-you-type” automatic translation suggestion, optional integration of machine translation, and quality-control features such as spelling, grammar, formatting, and terminology checkers. By enabling the reuse or recycling of legacy translation segments, TM tools help translators to work more quickly with less mental effort and to ensure greater consistency in and across translations, whether working alone or as part of a team (assuming that the materials being translated present a

significant amount of repetition). Consistency, however, is a two-edged sword: If the translation is defective, it will be defective consistently.

Terminology Extraction Tools and Alignment Tools

The notion of reuse on which translation tools are based presents several inherent limitations. Terminology databases and translation memories are created and filled by translators as they perform their work. Consequently, there is a time lag between the creation of a terminology database or translation memory and the point at which those resources reach optimal size and scope. Software designers addressed these problems by creating terminology extraction tools and so-called “alignment” tools. Terminology extraction helps the translator or terminologist save time by automating the identification and acquisition of term candidates. These tools use statistical and morphosyntactic algorithms to parse documents and acquire term candidates, which can then be validated and extracted for subsequent work in a terminology management tool. Along similar lines, alignment tools enable the creation of TMs from legacy translations performed without using translation memory. In an alignment tool, the user loads one or more source files and the corresponding target files and defines the segmentation rules. The tool then parses each source-language and target-language text pair, segments the content of the files according to the user-defined rules, and establishes a preliminary alignment. After confirming the correctness of the alignment and making changes as needed, the user can save the aligned text pair(s) or export the aligned segments to a new or existing translation memory, or both. Alignment enables translators to bootstrap the process of TM creation and development, but requires considerable manual effort. The decision to perform an alignment thus depends on the project parameters and the likelihood of receiving similar work in the future.

Standards

The development of competing TM tools, most of which stored data in proprietary formats, gave rise to a new issue, namely data exchange and interchange. To address this problem, the Localization Industry Standards Association created a number of open XML-based translation tool-related standards, including TMX (Translation Memory eXchange) for TM data; TBX (TermBase eXchange) for terminological data; SRX (Segmentation Rules eXchange), for sharing of segmentation rules across tools; and XML Text Memory (XML:TM) for the retention of document structure along with TM segments (Wright, 2006). In addition, XLIFF, the XML Localisation Interchange File Format from OASIS (the Organization for the Advancement of Structured Information), has been adopted as a native format by a number of tools and become an important tool-related standard.

Limitations in the Current Model of Translation Reuse

In the current market, translation typically occurs apart from, and subsequent to, the authoring of source materials. In other words, authoring and translation are perceived as two distinct processes, instead of two facets of multilingual communication. Because current authoring tools do not include support for terminology management or translation memory, authoring of source materials and translation of those materials require the use of separate tool-sets. Moreover, the functionality of TM tools is often linked to specific versions of authoring software such as Microsoft Office or Adobe Creative Suite. When new versions of authoring software are released, TM users need to upgrade their applications to be able to work with the new file formats.

Other limitations inherent in the current model of translation reuse are more fundamental. Because translation memory tools are designed to address the problem of repetition, they are not well suited to all text types. Of the eleven types of translation studied by Webb (1999), only four—commercial, legal, scientific, and technical—are well suited to the use of translation memory. The other seven types do not contain a sufficient proportion of repetitive content to benefit from the use of translation memory. The reliance on the sentence as the primary unit in the current model of translation reuse effectively undermines the ability to retrieve clauses, phrases, and other examples of subsentential repetition, as Macklovitch and Russell observe (2000). Sentence-level segmentation and the storage of translated segments as isolated sentences also prevents the translator from ascertaining the position of the segments in the context of the original source document; indeed, “the very notion of a document is lost” (Macklovitch & Russell, 2000, p. 140). The sentence-based approach also implicitly assumes that the sequence of segments—that is, the rhetorical structure of the document—is not an operative variable in translation. This may be true when translating highly technical procedural documents, but is not necessarily true for other types of material. Finally, the sentence-based approach also shifts the emphasis of translation away from texts and meaning to words and sentences, which ironically has been one of the major critiques historically leveled at machine translation. Empirical research indicates that the sentence-by-sentence approach of TM tools leads to an unnatural focus on the sentence, which affects both the task and product of translation (Dragsted, 2006).

Conclusion

The digital revolution, the Internet, and globalization have profoundly changed the scale, scope, and speed of communication, and in so doing, fueled a great increase in demand for professional translation (O’Hagan & Ashworth, 2002). Translation tools have emerged as critical productivity aids in response to this increased demand. However, the sentence-based model of translation reuse on which the current generation of tools is based is inherently limited. In addition, the current tool-set is designed to facilitate the translation of *documents*. However, the past decade has witnessed a shift from the authoring of documents to the creation of *content*, the advent of structured (semantic) authoring, and on-demand, single-source publishing, whereby content is increasingly divorced from context and presentation (Rockley, 2003; Gollner, 2009). It remains to be seen how translation tools will evolve in response to these developments.

Translation, Localization, and Internationalization

KEIRAN J. DUNNE

Translation, localization, and internationalization are interdependent processes whereby digital content and products developed in one locale are adapted for sale and use in one or more other locales. To understand the meaning of localization and internationalization and their relationship both to each other and to translation, it is necessary to consider when, why, and how they arose and the ways they have changed over time.

"The world's second oldest profession" (Somers, 2003, p. 11), translation remained relatively unchanged for thousands of years until the digital revolution and the rise of mass-market software. In the 1980s, thanks to the commoditization of the PC (personal computer), "typical users were no longer professional computer programmers, software engineers or hardware engineers" (Urien, Howard, & Perinotti, 1993, p. ix). US-based software companies realized that large markets were emerging for products such as spreadsheet programs and word processors that would enable average people to work more efficiently. Efforts to tap nascent mass markets soon moved beyond improving software reliability and user-friendliness to targeting international users by offering products in their language. "For a software product to have wide market acceptance in a non-English-speaking environment, it was essential to convert the software so that users saw a product in their own language and firmly based in their own culture" (Urien et al., 1993, x).

Adapting software for international markets was initially characterized as "translation on the computer for the computer" (van der Meer, 1995). However, it quickly became apparent that this work was "related to, but different from and more involved than, translation" (Lieu, 1997) because it encompassed not just translation of the interface but *all* local market requirements for culturally dependent representation of data, including character sets and encodings (scripts and glyphs), sorting rules, date formats (MM/DD/YYYY vs. DD/MM/YYYY, etc.), calendars (e.g., Gregorian, Hijri, Japanese Emperor Era, etc.), and decimal separators (comma vs. period), among other things. In software engineering, these local market requirements are collectively designated by the term "locale." Locales are designated as "language-country pairs; for example, French-Canada is one locale, while French-France is another" (Cadieux & Esselink, 2002). In the late 1980s, adapting software for international markets thus came to be known as "localization." By 1990, the provision of localization service was perceived as a distinct industry, as evidenced by the creation that year of the Localization Industry Standards Association (Lommel, 2007, p. 7).

To software companies, the incremental costs of localizing products seemed minimal compared to the size of the markets to which the localized products would provide access. However, initial localization efforts were complicated by the fact that the process occurred separate from, and subsequent to, the development of the original products (Esselink, 2003b, p. 4). This "localization-as-afterthought" approach proved problematic for several reasons. First, localization teams often had to return products to the development teams to enable translation and localization (by implementing support for the display of Asian languages, for example). Second, the translatable text was embedded in the software source code. Identifying and locating translatable text proved very challenging to localization

2 TRANSLATION, LOCALIZATION, AND INTERNATIONALIZATION

teams that had not been involved in the development of the products. Finally, because localization involved modification of the source code, creating X localized versions of a product required X corresponding sets of code, each of which had to be localized, compiled, tested, debugged, updated, and managed separately (Luong, Lok, Taylor, & Driscoll, 1995, p. 3). The development, maintenance, and support of multiple localized versions thus proved prohibitively complex, time-consuming, and costly.

Not surprisingly, technological complexity was the hallmark of early localization efforts. Software localization involved many more activities than traditional translation, including multilingual project management, software and online Help engineering and testing, conversion of translated documentation to different formats, as well as translation memory creation and management (Esselink, 2003a, p. 69), and these activities required the use of a wide variety of specialized software tools. Localization thus required strong technical and instrumental expertise in addition to traditional translation expertise and domain knowledge. "Throughout the 1990s, the localization industry tried to turn translators into semi-engineers," observes Esselink (2003b, pp. 6–7).

This trend was relatively short-lived, however. Driven by a desire to improve their return on investment, companies soon realized that "certain steps could be performed in advance to make localization easier: separating translatable text strings from the executable code, for example. This was referred to as *internationalization* or *localization-enablement*" (Cadieux & Esselink, 2002). Internationalization is an engineering process that precedes localization: "the goal of internationalization is to have software that can run anywhere in the world without having the source code changed or recompiled for different languages and local conventions" (Luong et al., 1995, p. 3), thus lowering the effort and cost of localization and increasing the speed and accuracy with which it can be accomplished. In practice, internationalization involves the separation of the culturally dependent contents of the user interface that may require modification, known as *resources*, from the core of the application and their storage in one or more *resource files* that are linked to the application (Hall, 1999, p. 298).

Resources in a typical program include bitmaps, icons, menus, dialog boxes, string tables, and accelerator tables (see Figure 1). Bitmaps are graphic files such as toolbar buttons. Icons are small images that represent and provide shortcuts to the program and to files created using the program. Menus are lists of commands that display at the top of the main program window. Dialog boxes are secondary windows within the program that display information (e.g., status, error and warning messages) and/or request additional input from the user. A string (short for "string of characters") is text that is stored and displayed as a group. Strings include menu items, command button captions, dialog box title captions, and status messages. Finally, accelerators are shortcuts that enable users to execute standard commands in Windows by simultaneously pressing the Ctrl key plus a specific letter on the keyboard.

Today, most locale-dependent aspects of data presentation can be managed via internationalization features built into host operating systems or by using development frameworks and runtime environments that offer extensive internationalization support, such as Java (Deutsch & Czarnecki, 2001) or Microsoft's .NET Framework (Smith-Ferrier, 2007). If the software has been properly internationalized and no translatable text is embedded in the source code, the localizer works only with resource files and does not touch the functional code of the application. Consequently, translation of strings in menus, dialog boxes, and string tables now comprises the bulk of the hands-on work of software localization. In some cases, depending on the source and target languages and the specific internationalization strategies employed, the localizer may also need to resize dialog boxes to account for translation-related string expansion. Visual localization tools allow users to view resources in context as they perform the nuts-and-bolts work of translating strings and

Figure 1 Localization of a sample application called Scribble using a visual localization tool. The left pane displays the localizable resources, the central pane displays the selected resource in visual mode, and the right pane displays the corresponding source and target strings in tabular format. Scribble © 2010 Keiran J. Dunne

resizing dialog boxes, and to use translation memory and terminology management tools during the process.

The fact that internationalization and the use of resource files enable software developers to address most locale-related issues upstream in the software development process, *prior to localization*, raises the question of what precisely distinguishes localization from translation today. Given that localization in practice consists primarily of translation of strings, it would seem that the term has come full circle and once again essentially means “translation on the computer, for the computer.” In fact, the blurring of the boundaries between translation and localization suggests a *convergence* of these processes is occurring as authoring and publishing undergo an evolution similar to localization.

Historically, authoring and publishing were distinct processes and professions. In the 1980s, however, digital authoring tools such as word-processing software appeared that were “designed to make it easy for authors to make documents look good. In doing so, they [turned] authors into desktop publishers,” notes Rockley (2003, p. 165). Much like early localization efforts that required changes to the source code, desktop publishing made content reuse difficult. Content reuse requires format modification and conversion, which tends to be labor-intensive and may require the creation of custom programs (Rockley, 2003, p. 165). These problems were exacerbated by the advent of the Web and its evolution into an enterprise communication platform. Desktop-based authoring and publishing could not keep up with the velocity of change on the Web, and the need to provide documents and content in an ever-increasing number of outputs for an increasing variety of devices, including PCs, PDAs (personal digital assistants), smart phones, and GPS (global positioning system) units.

The past decade has witnessed the increasing adoption of XML-based authoring strategies (Savourel, 2001, p. 7; Rockley, 2003, pp. 159–71) and content management systems (Rockley, 2003, pp. 178–91) in response to these challenges. XML is an application-independent markup language that enables the separation of content and format. XML focuses on the structure of content and documents, not on presentation. Formatting is controlled by style information that is stored in separate files and applied to the content to create a document on the fly in response to a user request. Along similar lines, content management systems (CMS) are repositories “designed to manage ‘information chunks’ (generically known as ‘content’), usually no longer than a couple of paragraphs,” which are combined to create a customized document in response to a user request (Biau Gil & Pym, 2006, p. 11). Although translation of XML content or of information chunks stored in a CMS does not constitute “localization” as the process has been traditionally understood, “content translation projects are now often considered as localization projects simply because of the complex environments in which the content is authored, managed, stored and published,” as Esselink observes (2003b, p. 7). Complexity, once the hallmark of software localization projects, is now a defining characteristic of large-volume translation as well.

Finally, another fundamental characteristic now shared by localization and content translation is the fact that they do not involve translation of *linear text*, but rather translation of disembodied *strings* or *chunks* of text. “In understanding text, a reader must not only be able to integrate information within sentences but also make connections across sentences to form a coherent discourse representation,” as Rayner and Sereno observe (1994, p. 73). However, it is not always possible to make such connections while translating strings: “Due to their non-linear structure and lack of narrative thread, software programs cannot be ‘read’ in the same way as [traditional documents]” (Dunne, 2009, p. 197). The same can be said for XML content and CMS chunks. Translation of strings or information chunks is technologically simpler than traditional localization because it does not require translators to compile or build target files, but is cognitively more complex because it requires translators to construct a mental model of a text that does not yet exist.

Ultimately, the convergence of the terms “localization” and “translation” is symptomatic of the evolution of digital “texts” over the past 25 years. The translation of nonlinear text without context and “texts without ends” (Biau Gil & Pym, 2006, p. 11) raises profound questions for students, scholars, educators, and practitioners about the nature of translation and, by extension, multilingual communication in the digital world. As Esselink observes, “it looks likely that while translators will be able and expected to increasingly focus on their linguistic tasks . . . the bar of technical complexity will be raised considerably as well” (2003b, p. 7).

Translators' Code of Ethics

ROSEMARY ARROJO

Every translation promises to represent the original in a different linguistic and cultural environment, and often in a different time. The complex process that makes it seem possible necessarily raises questions regarding the propriety of the translator's performance. How does a translation do justice to the original? What should the translator do in order to produce a faithful translation? How should the domestic and the foreign relate to one another? In fact, it would be practically impossible to address either the theory or the practice of translation—on any level, in any context, for whatever purpose—without at the same time invoking some kind of implicit or explicit code of ethics that should guide translators and reassure us about the legitimacy of their activity.

In the more than 2,000 years of scholarship on translation produced in the West, ethics has been largely associated with demands of total fidelity to the source text and culture as the central principle informing the translator's task. Insofar as the Western tradition has been basically Platonic, and, thus, generally defined by the belief in the possibility of a clear-cut opposition between idealized originals and their faithful repetitions in other contexts, it relies on the view of translation as the transportation of the same meaning across languages and cultures and, consequently, must also search for ways to appease its own deep-seated anxiety about the risks involved in this potentially dangerous operation.

The implicit code of ethics for translators in this strong tradition must repudiate or repress any possible sign of their interference in the process of translation. An opposing set of views on the topic, which can be associated with the increasing dissemination of postmodern, anti-Platonic thought in the last three or four decades, is interested precisely in the differences that translations and translators unavoidably bring to the process of meaning construction that shapes cultural products and identities. When translation is recognized as an inevitable agent of change and transformation, its implications become essential not just for a redefinition of the translator's task and the codes that supposedly guide it, but for all of us interested in a broader understanding of the productive relationships it establishes between the domestic and the foreign.

The Traditional Conception of Translation: For an Ethics of the Same

There is no better example of the sacralization of originals that is part and parcel of the Western, mostly Platonic, Judeo-Christian tradition than the treatment usually given to religious texts. An appropriate illustration can be found in one of the first documents about translation known to this tradition: the letter written by one Aristeas around 130 BCE on the translation of the Hebrew Scripture into Greek undertaken in the kingdom of Ptolemy Philadelphus (285–247 BCE). According to Aristeas's version of the legend of the Septuagint, the translation was carried out by a select group of 72 translators who worked together in perfect harmony and made sure that they always washed their hands and prayed before approaching their task. Fully committed to "make all things symbols of righteousness and truth," the 72 translators finished their Greek "transcription" of the original in 72 days "as

if this coincidence had been the result of some design" (Robinson, 2002, p. 6). The suggestion that there was indeed some divine intervention in the process seems to have placated the fear that their version could somehow constitute an illegitimate representation of God's word, and also underscored the decision by "the leaders of the people" to turn the translation into another sacred original that should remain untouched so that it "might be preserved imperishable and unchanged always" (Robinson, 2002, p. 6).

Inasmuch as ethics in translation has been so inextricably related to the neutral repetition of the same, the reflection on the topic is dominated by reminders of the need to curb the dangers of difference, often associated with the translator's potentially improper handling of the original. In the *Essay on the Principles of Translation*, published in 1791 by the Scottish historian Alexander Frazer Tytler, for example, a good translation is defined as that "in which the merit of the original work is so completely transfused into another language as to be as distinctly apprehended, and as strongly felt, by a native of the country to which that language belongs as it is by those who speak the language of the original work" (Robinson, 2002, p. 209). Following this conception, Tytler implicitly proposed a detailed code of ethics that could be summarized by his three "general laws of translation": first, "the translation should give a complete transcript of the ideas of the original work"; second, "the style and manner of writing should be of the same character with that of the original"; and, finally, the translation "should have all the ease of original composition" (p. 209). If we consider them carefully, Tytler's "laws" appear to be far more demanding (and even less realistic) than the general principles that seem to have directed the Septuagint. While for Philadelphus's contemporaries it sufficed that the translation allegedly offered a legitimate—albeit divinely guided—"transcription" of the original, Tytler prescribed total fidelity *both* to the source *and* to the target languages and cultures, suggesting that the process of translation should miraculously erase any possible difference involved in the transposition of meaning across different languages, different cultures, and different time frames.

These notions and concerns have been at the core of the scholarship on translation produced in the West at least since the letter of Aristeas and are still in full force today. As George Steiner pointed out in 1975, "all theories of translation—formal, pragmatic, chronological—are only variants of a single, inescapable question" about the ways in which fidelity should be achieved (Steiner, 1975, pp. 261–2), a question that has hardly included or considered the translator's perspective and circumstances. Predictably, the issue of fidelity is also fundamental for contemporary professional organizations such as the American Translators Association (ATA), whose current "Code of Ethics and Professional Practice" (approved in October of 2010) establishes that their members accept as their "ethical and professional duty," first and foremost, "to convey meaning between people and cultures faithfully, accurately, and impartially" (http://www.atanet.org/membership/code_of_professional_conduct.php). Thus, also for the ATA, ethics in translation is practically synonymous with accuracy and impartiality. Placed in an ideally neutral space between the domestic and the foreign, between different people, different languages, and different cultures, translators and interpreters are viewed as mere bridges that should make it materially possible for meaning to travel, unchanged and untouched, from one side to the other. Therefore, in order to be ethical, translators and interpreters should remain invisible and neutral and, at the same time, appropriately apply some specific knowledge—of the languages, the topics, and the terminology involved—as well as have adequate access to professional tools and reference materials. (See also Chesterman, 2001; Howard, 2009.)

This conception of translation, like the ones behind the Septuagint and Tytler's "laws," implicitly proposes an unrealistic code of ethics that not only relies on the possibility of the repetition of the same, but also grossly downplays the translator's role in the actual production of translated texts. However, as the ATA document inadvertently shows, the

question of ethics in translation is far more complex than this conception might suggest. In fact, one cannot even begin to properly address it without taking into account the inescapable issue of the translator's agency and how it determines the choices without which there would not even be any translation. It is certainly significant that in the Association's "Code of Ethics" most of the principles following the initial recommendation regarding fidelity actually try to establish guidelines for translators and interpreters on how to be ethical in their inevitable partiality. The ATA's second principle appropriately suggests, for instance, that members should "hold in confidence any privileged and/or confidential information entrusted to [them] in the course of [their] work," a recommendation which involves at least some form of partiality: when translators and interpreters hold information in confidence, they have consciously chosen to pay allegiance to something or to someone, not to all those parties that might need or profit from the information.

Furthermore, as the ATA also seems to recognize, there are other elements to be considered by translators and interpreters regarding the ethics of their activity. It cannot be ignored, for example, that such professionals are usually paid for their work and that they often develop business relationships among themselves, relationships which do require them to privilege certain interests over others. Thus, the Association urges members "to define in advance by mutual agreement, and to abide by, the terms of all business transactions among [themselves] and with others." Again, it could be argued that what is recommended here is not the application of an ethical guideline that could miraculously guarantee impartiality and protect all the interests at stake in such exchanges but, rather, that professionals become aware of their interests and those of others and, thus, choose and negotiate what interests should be honored by those involved.

Since translation never takes place in a vacuum, and since it is not possible for translators and interpreters to be equally faithful to *both* the original *and* the target languages and contexts, or to protect all the often-conflicting interests of those represented in these different positions, they cannot be exempt from having to make choices in every aspect of their work and, thus, from being partial in what they do. And this is precisely why ethics is such a fundamental issue not only for translators and interpreters but, also, for those who study the mechanisms and the impact of their activity.

A Postmodern Conception of Translation: For an Ethics of Difference

The overall foundation of a postmodern, anti-Platonic framework for translation is the notion that language works as an instrument that inescapably creates and disseminates, rather than merely communicates, meaning. As it questions the belief in the possibility of clear-cut oppositions between content and form, the original and its repetitions, the interpreter and what is being interpreted, an anti-Platonic conception of language will necessarily consider the reader's or the translator's perspective as a constitutive agent in the process of meaning construction. Therefore, translation can no longer be conceived in terms of an impersonal transportation of stable meaning across different languages, cultures, and contexts, but is recognized, instead, as a form of transformation, a "regulated transformation of one language by another, of one text by another" (Derrida, 1978, p. 20), the limits of which are decided and implemented by translators and their contexts and circumstances.

Once the translator's intervention is acknowledged as the element that fuses and transforms the foreign into the domestic, or vice versa, we can also begin to consider a different code of ethics for the profession in order to make it possible for meaning to travel and be transformed elsewhere. Basically, it would recognize the impossibility of erasing or repressing difference in both the process and the product of translation, and, consequently, redefine

the translator's role, which could no longer be described as a passive bridge between the domestic and the foreign. If translators stop hiding their authorial role behind vague notions of ethical impartiality, they will have to learn how to face the consequences of their visibility and be responsible for the choices they make and the allegiances they choose to cultivate in their work. In fact, from this perspective, it would actually be unethical and irresponsible for translators to insist on hiding behind claims of neutrality or to wash their hands of the responsibilities involved in the highly complex and influential work they do (Arrojo, 1998; Venuti, 1998).

The consequences implied by these views are far reaching and fundamental, not only for the theory and practice of translation but also for translator training, which, more than ever, should concentrate on the vital importance of ethics for the profession and strive to enable future translators to become more aware of their authorial role and to take on the responsibilities that it brings. Furthermore, one might consider that this new code of ethics for translators should also involve an explicit effort to educate clients, readers, critics, professional organizations, and all those who are directly affected by their work on how to reevaluate the opposition that tradition has built between originals and translations (Arrojo, 2005). These issues and the possibilities they have created for a broader understanding of what a translators' code of ethics might entail have also been the object of a growing, interdisciplinary trend in the humanities and social sciences that recognizes the essentially political role of translation in the construction of cultures, identities, and global relationships, thus serving as a valuable instrument for a better understanding of the ways in which the domestic and the foreign, the national and the global, the dominant and the subaltern, or the past and the present, relate to and are shaped by one another. (See for example, Bermann & Wood, 2005; Bachmann-Medick, 2009.)

Trimble, Louis

ELAINE TARONE

Louis Preston Trimble (1917–88) was a leader of the American “Washington School” of rhetorically based research on English for science and technology (EST). EST mostly concerns English-medium scientific and technical writing focused on facts and hypotheses about facts, and includes journal articles, teaching textbooks, and technical manuals (Trimble, 1985, pp. 5–6). The Washington School was a group of scholars at the University of Washington in Seattle between 1967 and 1988 who were then considered “the only serious and influential” group in the USA working on EST (Swales, 1985, p. 58). Trimble led this group in the development of the “grammatical-rhetorical” approach, which fundamentally assumed that in researching scientific and technical language use, it is not sufficient to identify grammatical forms in isolated sentences; rather, it is important to identify the relationships between such grammatical forms and their rhetorical function in the discourse. Discourse is here defined as a collection of connected sentences and paragraphs that together make up a coherent, cohesive text. The “grammatical-rhetorical” EST researcher aims to study the rhetorical organization and functional content of EST discourse as well as its “rhetorical-grammatical” relationships—for example, the way tense markers function in such rhetorical devices as defining, classifying, describing, or evaluating information (Trimble, 1985).

Throughout Trimble’s life, he was also a writer of fiction (producing more than 60 titles: mysteries, westerns, and science fiction). During this period, he also earned a living by hog ranching, house painting, ditch digging, stump ranching, and accounting (Selinker, Tarone, & Hanzeli, 1981, pp. v–vi, 225–7). But his academic career began to flourish in 1967 at the University of Washington when he was hired by the College of Engineering in a groundbreaking program to teach specialized English as a second language courses for undergraduate engineering students. Almost immediately Trimble, working with Larry Selinker, realized that they knew very little about the particular characteristics of the English register used in engineering. As teachers, they took it seriously when their students brought in text samples from engineering books or research articles in which grammatical use did not accord with sentence-level rules they were learning in ESL grammar books. “Our research began with an effort to determine the essential nature of scientific and technical English by finding its major characteristics and where it differed (if it did) from other forms of written English” (Trimble, 1985, p. 1). In that research enterprise, Trimble and Selinker included Mary Todd (later Mary Todd Trimble) and graduate students like Robert (Bley-)Vroman, Thomas Huckin, John Lackstrom, and Elaine Tarone in a highly collaborative and innovative research project, led by Trimble, that produced many of the publications listed in the References below. It is probably fair to say that the subsequent research endeavors of all these individuals were profoundly influenced by their exposure to Trimble’s “rhetorical” approach to EST, which will be described below.

Trimble defined “rhetoric” in EST as the process of producing a piece of scientific or technical writing by choosing and organizing information for a specific set of purposes and a specific set of readers. This rhetorical process includes the sequencing of items of information, and the expression of the relationships that exist between these items. According to Trimble, the cognitive processes of EST rhetoric are structured in a well-defined, if implicit, hierarchical pattern, with several levels in EST discourse. Level A in

Trimble's framework designates the overall objective of the piece of discourse, such as to detail an experiment, or make a recommendation, or present a new theory or set of hypotheses. Level B consists of general rhetorical functions that can be used to develop the objective selected above. Examples of general rhetorical functions used to detail an experiment might be to state the purpose, report past research, state the research question, present the apparatus used in the experiment, present the procedures used in the experiment, and so on. Some of these Level B functions may appear as distinct sections of, say, a technical report. Level C consists of specific rhetorical functions that develop each of the general functions in B. For example, in accomplishing the general rhetorical function of presenting an apparatus, the writer might use one or more of these specific rhetorical functions: (a) description: physical, function, process; (b) definition; (c) classification; and (d) visual-verbal relationship. Finally, Level D consists of rhetorical techniques that show the relationships among the rhetorical units of Level C: orders (time order, space order, cause and result) and patterns (order of importance, comparison and contrast, analogy, exemplification, illustration) (Trimble, 1985, pp. 10–11).

Trimble used this framework for EST rhetorical processes not only to structure research, but also (and perhaps even primarily) to provide non-native English readers and writers with a framework to help them analyze and improve their comprehension and production of scientific and technical English discourse. A major problem for such learners, according to Selinker, Todd Trimble, and Trimble (1976), is that rhetorical information in scientific discourse is typically implicitly stated, because the writer assumes that the reader already knows the rhetorical conventions of the discipline. For pedagogical purposes, this means that learners need analytical tools so they can identify such disciplinary rhetorical conventions on their own. In a highly inductive pedagogical approach, Trimble used a "discovery procedure" to get his engineering students to use the general rhetorical process framework described above in carrying out the same kind of close analysis of scientific and technical texts that he himself did in his research for publication. Trimble's pedagogy included the core principles of individualization, parallelism, and the use of different categories of text as a focus of instruction. Individualization means designing a set of general assignments that could be used by each student in a given class to meet his or her individual needs. Parallelism means selecting a unit of EST discourse for focus that had exemplary rhetorical, grammatical, and lexical features and scientific subject matter at a level that is understandable by students from many fields of study. Useful categories of texts could be authentic, adapted, synthesized, or created, depending on the level and needs of the class. Particularly in helping engineering students to understand EST discourse, Trimble found it necessary to distinguish two types of paragraphs: the conceptual paragraph (all information selected by a writer to develop a core generalization) and the physical paragraph (the piece of text separated out on the page by spacing or indentation) (Trimble, 1985, pp. 44–51).

One of the most important steps that the research group led by Trimble carried out in analyzing a piece of EST discourse was

the determination of the rhetorical-grammatical relationships; that is, of the specific grammatical elements which appear to be governed by the rhetorical functions that writers choose to carry their information. This helps readers understand why a particular piece of grammar (for example, a verb tense or mood or definite article) is used in a particular text when this use may seem to violate the logic or the "rules" of the language. (Trimble, 1985, p. 70)

This tool of rhetorical-grammatical analysis produced some of the most startling and oft-cited research findings of the Washington School.

In one rhetorical-grammatical analysis, for example, Trimble and colleagues found that in research article literature reviews reporting related research, tense choices were made by many EST writers nontemporally—that is, their use of present, present perfect, or past tense to refer to the work of others was unrelated to the publication date of that work. Rather, their tense choice indicated whether they viewed the reported work as supportive of, or contradictory to, their own position: Present tense marked the supportive work, and past tense marked the opposite (Lackstrom, Selinker, & Trimble, 1973; Todd Trimble & Trimble, 1982). Trimble (1985) provides an authentic example of this kind of tense choice; in this text, a space scientist reports two studies this way: “Davis (1962) . . . deduced” but “Elvey (1957) . . . on the other hand . . . has observed.” The use of past tense for Davis and present perfect for Elvey, Trimble argued, has nothing to do with the publication dates of the studies being cited, but simply signals to the reader that the writer agrees more with Elvey’s observation than with Davis’s deduction (Trimble, 1985, p. 126).

A similar rhetorical-grammatical analysis showed that in astrophysics journal articles, passive voice is not used to indicate scientific objectivity, as ESL grammar books still tend to state; rather, writers’ selection of active or passive voice with verbs in a logical argument signals to the reader whether the verbal action is their own original contribution (active) or is a standard procedure in the field (passive) (Tarone, Dwyer, Gillette, & Icke, 1981). Rhetorical-grammatical analysis was also later used to examine article use in ESL (Huckin & Olsen, 1983; Todd Trimble & Trimble, 1985) and presupposition in technical writing (Selinker, Trimble, & Vroman, 1974), to analyze ESL learners’ difficulties in distinguishing passive and stative verbs in EST discourse (Trimble, 1985, pp. 115–18), and to teach the use of modals in EST discourse (Lackstrom, 1978).

Much of the work of Trimble and colleagues has subsequently been taken up and further developed by such scholars as John Swales, whose seminal and still useful volume *Genre Analysis* (1990) provides the useful construct of “discourse community” to contextualize Trimble’s “rhetorical” approach to EST and account for the social factors underlying it.

Louis Trimble was a scholar who was modest about his role in the field and went out of his way to involve others in his work and to foreground their accomplishments while minimizing his own. His work in EST was not motivated by ego or influenced by academic hierarchy. It was first and foremost focused on helping his international engineering students to read and understand the English language texts they encountered in their classes, and to write more comprehensible prose for their teachers and publishers. He involved his students in his pedagogy, regularly inviting them to bring examples of these texts into class along with their questions about what they found there, and he involved graduate students and other teachers in thinking about those questions as well as their own. In doing so, and in thinking seriously about what the answers to these questions might mean, he made a lasting intellectual contribution, moving the field of EST in America into new and exciting territory.

Tucker, G. Richard

RICHARD DONATO

For over 40 years, G. Richard Tucker (1942–) has contributed significantly to research in diverse domains within the field of applied linguistics and has provided inspiring leadership to the profession. His influential research is far-reaching ranging from early psycholinguistic research on various aspects of bilingualism (Cohen, Tucker, & Lambert, 1967; Tucker, 1968; Tucker, Lambert, Rigault, & Segalowitz, 1968) to his more recent work in sociolinguistics, heritage language learners, and assessment of innovative foreign language programs in the United States (Paulston & Tucker, 2003; Tucker & Donato, 2003; Tucker, 2004, 2007).

Tucker earned his BA in psychology in 1964 from Williams College, and his MA and PhD in psycholinguistics from McGill University in 1965 and 1967 respectively. Upon graduation from McGill and over the next ten years, Tucker served as a project specialist for the Ford Foundation in Manila, Beirut, and Cairo. Concurrent with his international work with the Ford Foundation in language education, Tucker was a member of the psychology faculty at McGill University where he quickly moved through faculty ranks and earned the title of professor in 1976.

During his tenure at McGill (1967–78), Tucker became a pioneer in the field of sociolinguistic approaches to second language acquisition, bilingualism, and bilingual/immersion education. Some of Tucker's most well known research on the comprehensive evaluation of the bilingual education project in the Quebec community of St. Lambert was conducted during this time. With colleagues Lambert and d'Anglejan, Tucker was among the first researchers to conduct longitudinal investigations of diverse aspects of French–English bilingual education in the elementary grades. His research included studies of the comparative achievement in subject matter learning in two languages (Tucker, 1975), functional proficiency and communicative skills of bilingual children (Genesee, Tucker, & Lambert, 1975), and the cognitive consequences of bilingual schooling (Bruck, Lambert, & Tucker, 1977). Tucker's research in this area has provided the theoretical and methodological framework for similar studies of educational innovations and has served as a basis for education policy on dual-language instruction worldwide.

While investigating second language learning and innovative immersion instruction in his North American home, Tucker maintained an active research agenda that contributed significantly to understanding linguistic diversity and language policy in developing countries around the world (Tucker, Taylor, & Lambert, 1970). He investigated attitudes toward linguistic diversity in Egypt and the Philippines (Tucker, 1969), ethnic group interactions in multiethnic societies (Tucker, Taylor, & Reyes, 1971), and the structure of English-language policy in Jordan and in China (Harrison, Prator, & Tucker, 1975).

After leaving McGill in 1978, Tucker became president of the Center for Applied Linguistics, a position that he held until 1991. While at the Center for Applied Linguistics, Tucker created a vibrant center of applied linguistic research, research documentation and dissemination, and professional support and services for language teachers. In recognition of his extensive work in building one of our most notable applied linguistics resource centers in the world, the Center for Applied Linguistics instituted the G. Richard Tucker fellowship. This fellowship provides applicants with the opportunity to work side-by-side with the center's researchers during four weeks over the summer months.

Tucker's research during his time as president of the Center for Applied Linguistics (1978–91) took a decidedly different turn from his previous work. During his presidency of the center, Tucker began to focus extensively on international aspects of language teaching, educational policy, and language planning. While maintaining his research and publications on bilingual education in North America, Tucker explored applied linguistic issues from a global perspective. His writings during this time reflected Tucker's desire to investigate the implications of research across national borders and instructional contexts (Tucker, 1979, 1981a), to establish a national research agenda for language education (Tucker, 1983a, 1983b), and to identify the ways to develop a language competent society here and abroad (Tucker, 1986, 1987, 1991). Additionally, Tucker's research reflected a clear sociolinguistic orientation to unraveling the emergent complexities of social policy and its relationship to second language acquisition in instructed contexts (Tucker, 1981b). Although his research and position papers expanded beyond the early days of the St. Lambert project to encompass now a broad worldview, Tucker remained anchored in the realities of the classroom and in the need for principled approaches to instruction based on the best available research evidence and psycholinguistic theory. With his colleague, Jodi Crandall, Tucker produced a series of studies on content-based language instruction that set the stage for research and theorizing in this area that has extended into the present (Tucker & Crandall, 1989; Crandall & Tucker, 1990).

In 1992 and following his presidency at the Center for Applied Linguistics, Tucker joined the Modern Languages Department at Carnegie Mellon University where he received the title of Paul Mellon University Professor of Applied Linguistics. In 1995, he became department head, a position he held until 2007 when he was appointed as interim dean of student affairs for the 2008–9 academic year.

Tucker remained a prolific scholar and researcher despite the demands of university administration. While at Carnegie Mellon University, his research reflects two areas for which Tucker is well known as an international authority, namely, language policy and planning and innovative second and foreign-language program development and evaluation. In his early years at Carnegie Mellon University, Tucker continued to write extensively on language policy and practice analyzing issues such as, the English-only movement, the education of linguistically and culturally diverse students, and the need for a language competent citizenry.

Reminiscent of his work in Canada with Lambert and colleagues, in 1994 Tucker turned attention to the development, implementation, and assessment of innovative foreign language programs in schools in the Pittsburgh area. With his colleague Donato and graduate students at Carnegie Mellon University and the University of Pittsburgh, Tucker initiated program development and research initiatives on the teaching of Japanese and Spanish to elementary school students. His collaborative research in this area is the first to investigate empirically foreign-language learning in US elementary schools (Donato, Antonek, & Tucker, 1996). His studies included investigations of the cumulative achievements of children participating in these programs (Tucker, Donato, & Antonek, 1996), attitude profiles of various constituencies and decision makers (Tucker, Donato, & Murday, 2001), and challenges that face the implementation of sequential language study (Donato & Tucker, 2007). His studies remain a primary source of information for school districts implementing foreign-language instruction across the grade levels.

Tucker has been recognized for his achievements with numerous honors and awards. To name a few, he was the recipient of the National Association for Bilingual Education (NABE) honoree of the year for significant contributions to the body of research on language acquisition and the establishment of sound bilingual education programs. In 1997, he was awarded the American Council on the Teaching of Foreign Languages Paul Pimsleur Award for his research on the comprehensive evaluation of foreign-language programs

in the elementary school. His extensive service to the profession was recognized with the James E. Alatis service award given by teachers of English to speakers of other languages. At Carnegie Mellon University, he received the Elliott Dunlap Smith Award for distinguished teaching and educational service in the college of humanities and social sciences. From the American Association of Applied Linguistics, he was awarded the Distinguished Scholarship and Service Award.

Tucker's extensive service record to the profession includes multiple year service as advisory board and executive committee member to organizations such as the International Research Foundation for English Language Education, the Summer Institute of Linguistics, and the American Association of Applied Linguistics.

Tucker continues his work at Carnegie Mellon University where he recently accepted the position of associate vice-provost for education at the university's Qatar campus. Tucker will reside on the Qatar campus beginning in August 2010 and plans to remain active in his research collaborations, student advisement, and professional service.

Turell, Maria Teresa

MARIA S. SPASSOVA

In many countries around the world forensic linguistics is a well-established discipline, which seeks to describe the existing interplay between language and law. Forensic linguists like to refer to their discipline in terms of three areas of study: language of the law (the study of legal and administration discourse); language of the court and the legal process (the analysis of linguistic varieties of all those actors involved in judicial settings, such as judges, lawyers, defendants, witnesses, police); and language as evidence (the use of linguistic evidence in linguistic profiling and forensic voice and text comparison to help a court decide on speaker identification, authorship attribution, plagiarism detection, and trademark litigation cases, among many others).

Maria Teresa Turell, who was born in 1949 in Barcelona (www.upf.edu/pdi/iula/teresa.turell/), started pioneer forensic linguistic work at the end of the 1990s with two main purposes: (a) to launch forensic linguistics in Spain and Spanish-speaking countries, and (b) to make the epistemological and methodological foundations of this discipline at an international scale more rigorous and reliable. Turell's work in forensic linguistics draws from her long-standing research activity in the field of sociolinguistic variation, language contact, and multilingualism studies, reflected in the many funded projects that she has coordinated (CICYT-BFF 1990-0580; CICYT-BFF 1993-0725; CICYT-SEC 1996-0627; EU-FABULA 1998; EU-FABULA 2000; DGI-BFF 2001-0820; DGI-HUM 2004-05404-02) and the numerous publications that have appeared in books, collective volumes, and national and international journals (Turell, 1987, 1990, 1991, 1995, 2001, 2003, 2005a, 2007a, 2008a; Casesnoves, Sankoff, & Turell, 2006).
